Work off campus? Learn about our remote access options The recent increase in the use of polymer composites has led to the need for higher production performance processes than is currently used in most thermoplastic composite industries. One way to improve performance in composite production is to use thermoplastic matrix sheet composites. This study examined the characteristics of the part that forms several thermoplastic composites. The fiberglass-enhanced composites based on polypropylene, nylon 12, poly (butylene terephthalate), poly (ethylene terephthalate), poly (phenylene sulfide) and poly (etheretherketon) were studied. The processing conditions required for the solid stamping of these composites have been defined. A temperature window was determined to stamp each of these composites, which correlated with melting and re-crystallization peaks as a result of a scan of differential calorimetry (DSC). P.K.
