Through Doppler you can estimate the flow of this artery, the resistance to the flow of this decreases during pregnancy, due to the trophoblast intrusion into the spiral arteries, so that we can make an assessment of this flow to see if it has been captured. DEVELOPMENT AND EVOLUTION The main feature in the flow of the uterine artery wave is protodiastolic cutting or noting. Who should not be present after week 24 of pregnancy. When a trophoblastic intrusion into spiral arteries does not occur, these arteries retain their vasomontal capacity, so there is a risk that a woman will generate a hypertensive pattern by generating pre-eclampsia. In the wave of the stream you will see protodiastolic incisor (cutting), still present after week 24. HELP (IN OPRAH ARTICLE) Espinosa J, K Kim Y YM, Romero R, Nien JK, et al.
