Reducing rubella incidence in the U.S. since the beginning of immunization. Maurice Hillman (1919-2005), creator of Triple Viral. For other purposes, see SPR (disambiating). The triple viral vaccine or triple viral vaccine (also known as SPR and SRP) is a mixture of three faded viral components administered to be administered for measles immunization (measles vaccine), mumps or mumps (mumps vaccine) and rubella (rubella vaccine). This is usually given to children aged about one year, from the steering wheel to the beginning of preschool age between the ages of four and five years. It is a regularly used vaccine worldwide. Since its introduction in its original versions of the 1970s, more than 500 million doses have been introduced in more than 60 countries. The effectiveness of reducing the incidence of measles from the use of the vaccine to the global spread of the measles vaccine, the incidence of this infectious disease was inevitable. Measles incidence has now fallen to less than 1% of minors in 30 countries who regularly use the vaccine. So far, the benefits of the measles vaccine in terms of prevention, disability and death have been well documented. In the United States, the measles vaccine is estimated to have prevented about 52 million new cases, 17,400 cases of mental retardation and about 5,200 deaths. In 1994 and 2004, a strategy led by the World Health Organization and UNICEF to improve vaccination coverage prevented an estimated 1.4 million measles deaths worldwide. Muedtitis is another viral childhood disease that has been very common in the past. Rubella, the middle part, also declined after the use of the vaccine, especially in the population of high-risk pregnant women, which causes birth defects in newborns. The Japanese government banned the vaccine in 1993, as well as the human papillomavirus, in 2013, after the number of adverse reactions was higher than expected, being the only developed country where it was banned. However, according to the British Health Service, the reason was that Japan used a vaccine variant with problems. Since the ban on triple viral vaccine in Japan in 5 years, several outbreaks of measles have killed 94 children. Calendar Triple viral vaccine against measles, mumps and rubella is administered subcutaneously up to two years of life, usually at the age of one year. A second dose of booster is needed to reach levels to disrupt the transmission of viruses. Strengthening can be granted a month or after one or more years, in accordance with the individual rules of each country. In 2005, a combination of a triple viral vaccine with a chickenpox vaccine was proposed to make it easier to introduce children's vaccines. Links to Babbott FL Jr, Gordon JE (1954). Modern measles. Data: No908104 Multimedia: MMR vaccine derived from Large text Triple viral vaccine protects against measles, mumps and rubella. The Triple Viral Vaccine Calendar is given in two doses: 12 to 15 months between 4 and 6 years of age. The U.S. can get the vaccine as early as 6 months. These children should receive the recommended normal doses between the ages of 12 and 15 months, and between the ages of 4 and 6 years (if they remain in an area where the risk of the disease is high, they should receive the first dose at 12 months and the second dose at least 4 weeks later). There have been recent outbreaks of mumps in the US. The outbreak is more than expected, this area is the area. If you have questions about vaccinating your family during an outbreak, contact your gp or contact your staff or your local health department. Why measles, mumps and rubella are recommended for vaccination of infections that can cause serious diseases. More than 95% of children receiving triple viral will be protected from three diseases for all Life. Possible associated risks Serious problems, such as allergic reactions, are extremely rare. Possible mild to moderate reactions include rash, fever, inflammation of the cheeks, feverish cramps and mild joint pain. When to postpone or avoid triple viral vaccination is not recommended if your child has had a severe allergic reaction to the previous dose of the same vaccine or vaccine components, including gelatin and antibiotic neomicine. you have a disorder that affects your immune system (such as cancer), which is currently medicated with steroids or other drugs that weaken your immune system by receiving chemotherapy or radiotherapy Talk to your child's doctor about whether it is convenient to give him a triple viral if: he is sick when he is going to be vaccinated. A simple cold or other minor illness should usually not prevent the child from emptying. You received any other vaccines in the previous month because there are some vaccines that may interfere with the effectiveness of triple viral ever had a low platelet level Your child's doctor may believe that the benefits of vaccinating it outweigh his or her potential risks. Pregnant women should not get triple viral until they are born. Taking care of your child after vaccination If your child develops a skin rash without any other symptoms, it does not need treatment. The rash will disappear in a few days. Talk to your child's doctor about whether he or she can give you acetaminophen or ibuprofen for pain or fever and tell him what the appropriate dose is. When to call your child's doctor, if you doubt whether to delay or avoid the vaccine. Call him also if problems arise after vaccination. Review: Elana Pearl Ben-Joseph, MD Review date: March 2019 Measles - is a feverish flare-up that can occur at all ages, being more severe in children under 5 years of age or malnourished, in which it can cause serious respiratory complications (such as pneumonia), central nervous system diseases (such as convulsions, meningitis, blindness) and diseases with chronic brain term. Rubella is a viral disease that can occur in adults and children. When a receptive pregnant woman is exposed to the virus, it can lead to stillbirth and neonatal death and congenital rubella syndrome with severe malformations in newborns that cause deafness, blindness and congenital heart defects. Pig or mumps is a viral disease characterized by inflammation of the parotid glands (salivary glands). Can cause complications such as orchids pancreatitis, encephalitis and others. Double Viral What Does It Protect From? Measles measles is a feverish flare-up that can occur at any age, being more severe in children under 5 years of age or malnutrition, in which it can cause serious respiratory complications (such as pneumonia), central nervous system diseases (such as convulsions, meningoencephalitis, blindness) and late diseases with chronic complications. Rubella is a viral disease that can occur in adults and children. When a receptive pregnant woman is exposed to the virus, it can lead to stillbirth and neonatal death and congenital rubella syndrome with severe malformations in newborns that cause deafness, blindness and congenital heart disease. Triple viral vaccine protects against measles, rubella and mumps or mumps. Vaccination StrategyWeast National Vaccination ScheduleFirst dose: 12 months Secondary dose: 5 or 6 yearsAdults: must accredit two doses of the vaccine with the measles component. For 5 years, adolescents and adults must accredit at least two doses of measles vaccine (monovalent, double or triple viral) used after a year of life, or confirm through laboratory research the presence of antibodies to measles. People born before 1965 do not need to be vaccinated because they are considered protected because they are in contact with the virus.
