FortiClient by FortiNet is a security solution ideal for small and large businesses. It offers antivirus for endpoints, VPN access and software inventory management. FortiClient offers an all-inclusive security solution with VPN access, endpoint management and antivirus protection. FortiClient provides you with all the tools you need to keep your computer safe. The endpoint management solution helps identify and control software installed at a specific endpoint. If the software is installed at the end point that is not business-related, then you may have unnecessary vulnerabilities entered into your network. FortiClient helps ensure that you can control these third-party application installations. FortiClient makes remote access simple and easy for all users. It offers the remote user an improved experience. The VPN solution uses SSL and IPsec encryption to allow the user remote access from almost anywhere in the world. It also includes features such as automatic connectivity and constant connectivity. Antivirus protection is mandatory. This helps to combat all potential exploitation that can invade your network security. FortiClient offers excellent antivirus protection software that is included in the initial setting by clicking on the advanced options. FortiClient also provides protection against exploitation, protecting against all types of malware, ransomware and viruses. It even protects against zero-day attacks that have not yet been detected. Is there a better alternative? There are many alternatives to choose from. These include Avast, McAfee, WatchGuard and Kaspersky. However, these alternatives are simply not enough. FortiClient does a better job of keeping you covered on all fronts. Where can you run this program? This program can be launched in Windows, Mac, and Linux environments. The website provides a customer for each system. Fortunately, the software won't slow down the computer. FortiNet provides a fantastic solution for individuals, small and large businesses. It's a great choice for easy VPN access, endpoint management and antivirus protection. Should you download it? Yes, this software is recommended. Once installed, your computer and network will be protected from external threats. You will feel more relaxed using your computer. Stephen Lilly If you installed a game on your Mac that you no longer play or were just generally dissatisfied, you can delete this game in just a couple of minutes. This frees up space on the hard drive of your desktop or Mac laptop, making room for more files or even Games. The removal process is similar to the process you can go through to remove the game from your Windows computer. Open the computer hard drive icon on your Mac OS X desktop. Select Apps to see a list of all installed apps on your computer. Your games will be among the Listed. Click the icon for the game you want to remove. Drag the icon over the Trash icon on the dock at the bottom of the screen. Release the game icon to the Trash icon. Click Finder at the top of the screen and then Empty Cart... to finish deleting the game from your Mac computer. Java is and has always been the source of many ills. And security holes. There are a lot of security holes. There's really no reason to have it installed anymore, especially now that Minecraft has its own Java kit for OS X and Windows. So today is the day you remove it. ANSWER: Java is insecure and horrible, it's time to disable it, and here's how if you delete it and find out that one of your applications depends on Java and won't work anymore, it's easy enough to reset it again. Or stop using this app and find a better alternative. But in any case, a Java unidentified car is not going to break your computer forever. Removing Java Runtime is easy enough. Open the Terminal window and insert the following two lines. You will be asked the password. `sudo rm-fr /Library/Internet/Internet plug-ins/JavaAppletPlugin.plugin sudo rm-fr /Library/PreferencePanes/JavaControlPanel.prefpane` Ready! You can now close and reopen the System Preferences window to see if the icon has disappeared. Removing the Java JDK (which can't be installed) java development kit is different from the running time, and to remove it, you need to run another command and look in another folder to see if it's even installed (usually it's not). Open the Terminal window and enter (or insert) the next command to switch to the correct folder: `cd/Library/Java/JavaVirtualMachines` And then use `ls` on request to see if there's anything there. In my case, it was. Then you ins throw in the following: `sudo rm-fr jdk1`, and then use the TAB key to make the shell complete the file name. This should look like the next screenshot, but the number may be different in your case: This should be all you have to do. You should've noticed that closing and re-opening system preferences is enough to make the icon there go away, but to be really sure, you can open the terminal and just enter Java. You will be presented with a message: No Java time running now, asking to install. And then a small dialog box will pop up with the OK button highlighted, indicating that everything will be fine now. We've also looked at how to remove Java from your Windows computer if you want to do so. You've seen it on a lot of PC help sites. Remove fonts to speed up your computer! Don't follow this advice - it's a myth. The insets are a tip to fix a problem to fix a specific problem general performance advice to speed up your computer. Of course, installing thousands of fonts is a bad idea RELATED: 10 Windows Tweaking myths are debunked Like many myths, there is a core of truth here. You don't want to install too many fonts on your computer, as this can slow down the process. Start installing thousands of additional fonts on Windows, Mac or Linux PC, and you may see a noticeable slowdown. Fonts don't just slow down your computer altogether, however. Having too many fonts can slow down the download process down a bit as these fonts are loaded into memory, of course. But you'll notice too many fonts in other situations. For example, launching apps such as word processors can take an unusually long time. The Font menu in apps can take a long time to appear and is usually slow. You will probably start to see that slowing down to more than 1000 fonts. The default fonts and even a few extra fonts you can install definitely won't slow anything down. On the new Windows 10 system, we see 78 fonts - the number is displayed at the bottom of the font control panel. Uninstalling some of these fonts won't speed up your computer. Even if we saw hundreds of fonts, it would be fine. Don't just start deleting random fonts! Even if you've installed too many fonts and they slow down your computer, you don't need to delete fonts one by one. Ignore any tips that tell you to go to the font folder and just start deleting fonts. Of course, if you set certain fonts and you remember which ones you installed, you can delete them one at a time. But don't just try to accidentally delete fonts. If you're experiencing a slowdown due to too many fonts, you should just reset your Windows or Mac system back to default. This will remove any third-party fonts installed on your computer and restore the system's fonts by default. Again, you don't have to do this in most situations, especially if your computer is working properly. Third-party programs can install their own fonts they want to use, and restoring the default set will remove them. However, this will restore any default system fonts you may have deleted if you have followed this bad advice in the past, so this is useful advice anyway. How to restore Windows fonts by default to reset fonts back to default state on Windows, use the font control bar. This process works on Windows 7, 8, 8.1 and 10. Open the control panel window and go to the look and personalization of the fonts. Click the font settings button on the left side of the window and then click the default Font Settings button. Your fonts Reset by default those Windows came with. How to restore Mac fonts by default to restore default fonts on the Mac, use the Font Book app. Press command and space to open the spotlight dialogue, enter the font book, and click Enter to open it. Click the File menu in the font book and select Restore standard fonts. Your fonts will be reset to the default fonts included in MacOS. If there is a program delayed on Windows Add or delete a program list that doesn't belong, there are two simple tricks you use to clear it from the list and tidy things up. The Add or Delete Programs list shows all installed software on your Windows computer. In an ideal world, the only apps that are currently installed will be displayed there, but sometimes the phantom list is saved even after the program is gone. Maybe you manually removed the program (which removes the delete Windows app attempts to call later when you use the add/delete feature), maybe some files are corrupted, or maybe the delete was just poorly implemented by the creator of the software. RELATED: What does CCleaner do and should you use it? No matter what created the phantom record, it's easy to delete either after a few quick edits to the Windows registry or using the popular CCleaner app to do the task for you. By all means, try the CCleaner method first, because it's fast and pretty much reliable. If, for whatever reason, it doesn't work (the software problems that got most of us into this mess in the first place after all), you can follow up on manual registry editing. Let's look at both methods now. Clean Up Records with CCleaner To use CCleaner to clean your Add or delete the program list, just download the app from the Piriform website here and run it. Once you start it, click on the large Tools tab in the left navigation glass. In the Tools section, select Delete, and then select from the list of programs that you want to delete the record for. Select delete button. Delete, unlike Uninstall, will simply remove the entry from the program list and will not attempt to remove any installed software or bits left after manual removal. Reboot your computer to allow the changes to take effect. Cleaning Records with a manual registry rights If for some reason the CCleaner method doesn't work (or you just want to do it manually), it's in the registry we go to. Hang the regedit in the Start Menu Launch box to run the registry editor. Inside the registry, we're going to make two potential stops (depending on whether you're working a 32-bit or 64-bit version of the windows). First stop for all Windows users. In the editor, use the left navigation panel for the navigation panel to navigate the structure of the registry catalog in this location: In this registry directory, you'll see two types of records: software ID input and human-read software The first type of records requires more effort to identify: You will need to click on each individual entry and search for the name of the software in the description panel, labeled DisplayName, as shown below. Here we see that the registry key 079FEF6F-9E83-4694-897D-69C30389B772 corresponds to the add/Remove list with the tag Python 3.6.1 Add to Path. Before you invest too much time in checking the DisplayName setting of all program records with abstract ID, scroll down until you reach the names you read and quickly check them for the software you're looking for. Once you find a record for a piece of software that you want to remove from the list, just click on it and select Delete on the registry key for the app. The second stop, for users. Working with the 64-bit version of Windows, is a completely separate subcategory in the registry located at: HKEY\_LOCAL\_MACHINE\SOFTWARE-Wow6432Node-Microsoft-Windows-CurrentVersion\Uninstall Here you will find, if the records for applications are present, exactly the same catalog structure as we found in the previous catalog Delete in which some entries will be identified by an abstract ID, some will be identified by an abstract ID. Don't worry, if there's no entry here for the app you just deleted in the previous section, not all apps have records in both registry directories. Once you remove the relevant records for the apps you want to delete, reboot the changes to take effect. That's all there is to it. Whether it's because of a deletion failure or because you've got a little overexcited and manually removed directory programs, with cCleaner and the registry editor at your fingertips Add and Delete program list is clean and up to date again. Once again.
