Photo: ShutterstockIf you make a meal with lots of ingredients that require washing, peeling, and chopping, chances are you have to create a misens in place. Organizing all your ingredients into neat little piles (or ramekins) means you can follow the recipe at the required pace, without pausing to tinker. The order you cook misens in doesn't matter that much, with one caveat: you should absolutely prepare the onion last. Mise en place is a French phrase that roughly translates as everything in its place. How Cooking Food More As we all know, onions are full of pain. Once you tear their cell walls, they take revenge by releasing enzymes that reshape into various compounds, including syn-Propanethial-S-oxide, a compound that makes you cry. (It is, for all intents and purposes, tear gas.) Obviously you want to hang out with this dude for as little time as possible, so chopping onions (or worse, shallots) should come dead last in your training, so you don't have to cry your way through or wear dorky glasses during the process of chopping carrots, root vegetables, herbs, and everything else going into your recipe. One exception to this is when knowing that you need to caramelize these onions before you can proceed with the recipe. Caramelization, as we all know, takes longer to expect, so chop the onions and get them into the pan to start the whole process and then finish the rest of your misanthrope. CABOT, Vt. - Last week, we put the finishing touches on our new Glenwood wood-burning stove. In fact, there isn't much new about our Glenwood; it was manufactured sometime at the turn of the century and I'm not talking about 2000. We bought it in Rhode Island from Emery Pineo, an opinion but fascinated guy who restores these ol' beauties for a living. Not content to leave well enough alone, we rigged our Glenwood Solar with hot water loops. It's a fairly simple operation, although I hired a friend to sweat the joints, since my plumbing skills are in the toilet (pun intended). Since we already had a water pre-heating tank in the basement for our solar hot water collectors, we decided to use a circulator to push water through the fire box and into the tank (many off-gridders use a thermo-siphon system in which heated water rises into a tank installed above the stove, eliminating the need for a pump). We have connected the thermostat to regulate the circulator, which draws only about 2 amplifiers per 24 volts. The results are still mixed. The system works as it should; it just doesn't produce the kind of temperature we expected. When the oven is cranked, we heat our water to about 80 degrees. It's definitely taking a chill (and thus reducing the load on propane water heater). But this is not the production of scalding hot water we were looking forward to. I think the problem may be The circulator just pushes the water through the fire box too fast, it's not there long enough to pick up a lot of heat. With a thermo-siphon design, the water rises only when it has reached a fairly high temperature. This is only a theory at the moment; I have more research to do. -BEN Hewitt (CLICK TO ENLARGE) This content is created and supported by a third party and is imported to this page to help users provide their email addresses. The Portland Framework Tower, one of the most interesting high-wood projects on the boards, was cancelled due to financial considerations. The 12-storey Lever Architecture building was one of two winners of the competition to support the study of high-rise wooden buildings. In our previous post on it, Framework Tall Wood Tower in Portland sprouting soon, Thomas Robinson of Lever gave one of the most memorable descriptions of why we should build from a local tree, and how it might change the way we think about building: Connecting directly with people who were doing materials for the project resonates with me in the same way the farm table to the movement has changed the way we treat our food. As a firm, we are very driven by ingredients - materials that go into building. This forest-to-frame approach, as we call it, has led us to search for projects that change the way people think about wooden construction. © Lever Architecture/Lobby there were hints of trouble in January when Rachel Monahan of Willamette Week noted that it was attracting critics because it would be much more expensive than building traditional concrete and steel structures. The Framework was supposed to be a catalytic project that would serve as a national example, but it was controversial because of its cost. It will be an expensive test case in which two-bedroom apartments measuring just 660 square feet will cost $567,389 each to build, according to calculations by the county's Housing Authority Home Forward, which include a portion of the total area attached to each apartment. Monahan also noted that the funding deficit is about $2 million. This has never been closed, and in a recent article, Monahan writes: The Housing Bureau justified the decision to spend city dollars upgrades on the project, in part, saying that the project was ready to go, including funding. But it wasn't. The project faced a $2 million funding shortfall that was not filled. Amanda Coulson Hurley, who wrote a stunning article about the building late last year, received this message: ©. D.R. Johnson

there are a lot of crazy-changing Conditions are happening right now; Lumber rose from US$315 at the beginning of 2017 to US$540 earlier this year, thanks to increased demand the hot American economy and the big tariffs imposed by the Trump government on Canadian lumber. Cross-laminated wood (CLT) uses a lot of wood, so a big increase like this will make a difference. Alternatives, steel and concrete, are also spiked because of tariffs, usually making all types of housing less affordable. CLT is still new and expensive, and between tax cuts that ignited the fire within the economy and tariffs that ignited the fire on materials prices, it's a difficult time to try to build non-profit housing at a fixed price. The developer is trying to put a bold face on it, saying: While facing market challenges beyond our control, we are very proud of the achievements of the Framework and the new standards that we have created for the use of CLT in the US. Lever Architecture/ through But in fact, it's a huge setback for a tall tree in North America. There were so many attributes in this project that could be admired - the way it promoted local wood, increasing density, capturing carbon and helping to create a whole new industry around cross-laminated wood. What a shame. Beth Bischoff stand with hip-width legs apart, knees bent, and keep the medicine ball outside the right knee (a). Keep your hands straight, brace your core and stand as you lift the ball diagonally above your left shoulder (b). Pause and then come back to start. It's one representative. Make five, and then switch to the other side. Fast tip: Choose a medicine weight ball that challenges your core for the last few reps without sacrificing proper shape.
