Understand different versions of the file if you are reading this, there is a good chance you are trying to download an app from the Mirror APK, which is a legitimate hosting site for APKs that are available for free in the game store. This is a great option if the app you want geo is limited is not available for your device, or has an update that hasn't yet reached your account. Related: How to Sideload apps on Android if you find yourself, then trying to figure out the right download for your phone can be without any. If the app you're looking at only has one version, don't worry about that, but some apps have multiple versions available—youtube has 40 different types, for example. That's when you need to know what version is best for your phone. Generally the details are broken down into three basic categories: architecture: this refers to the type of processor on your phone. Usually the options are arm, arm64, x86 and x86_64. ARM and x86 are for 32-bit processors, while x86_64 for 64-bit processors. Below we will explain in more detail. Android version: This version of your device's Android operating system is running. DPI screen: DPI stands for dot-per-inch—basically this is the pixel density of your phone's screen. For example, a full six-inch HD (1920×1080) screen has a DPI ~367. Bump Resolutions up to 2880×1440, and DPI increases to ~537. Technically, the correct terminology when referring to pixel density should be PPI, or pixels per inch. But since APK Mirror (and others) name this as DPI, we stick with relative idioms. ARM vs. x86 While the Android and DPI versions are very up to right, the cpu architecture is another story altogether. I'm trying to break it here as much as possible: it's a mobile processor architecture first and for all, and what the majority of phones are running right now. Qualcomm's Snapdragon, Samsung's Axinos and MediaTek mobile chips are all examples of ARM processors. Most modern chips are 64-bit, or ARM64. x86: This is the architectural specification for Intel chips. As dominant as Intel is in the PC market, these chips are far less common on Android phones. x86_64 also refers to Intel's 64-bit chips. This information is particularly important because the x86 and ARM files are not compatible—you should use the version designed for your phone's specific architecture. Similarly, if your phone is running a 32-bit processor, the 64-bit APK won't work. The 64-bit but backward processors are compatible, so the 32-bit APK will work well on a 64-bit processor. How to find the correct information of your device I know, I know, it's confusing. The good news is that there is an easy way to find all your device information with an app called Droid Data Hardware. This is a free app in the game store, and you basically tell everything you need to know about your phone. Go ahead and give it up and install and fire it. We'll show you exactly what you're looking for, the first tab you want to look at is the device tab, which is what the app opens on by default. There are two key pieces of information here: the DPI and Android OS version. To find DPI, look at the software density input under the display section. For the Android version, look at the OS version under the Device section. It explicitly displays the version number. For architectural information, slide over to the System tab and check out the architecture processor and input set instructions under the CPU tab. This one is not quite as straightforward as others since it's not explicitly arm64 or similar, so you should read between the lines a little bit. First of all, if you see 64 in the architectural name, you can almost guarantee it's a 64-bit device. To find out if it's ARM or x86, you'll look at the tutorial set section—again, you're just looking for basic information here, like arm letters. In my Pixel 2 XL (images above), for example, it's an ARM64 device. Nexus 5, however, is not quite as clear—we can see that it is ARM, but it does not explicitly show As a 32-bit processor. In this case, we can safely assume that it is a 32-bit chip because it does not specify a 64-bit architecture. Choosing which file to download with it in mind, let's go back to our YouTube example above. We are going to look at many YouTube versions in mirror APK and find out exactly which download applies to my Pixel 2 XL. With device information at hand, we know that it is running a 64-bit ARM processor, has a DPI of 560, and is running Android 8.1. It's easy to match the cpu type and Android version—arm64 and Android 5.0+. But there is no specific option for 560dpi. Therefore, we have two main options to choose from: the highest DPI available - in this case, 480, or nodpi. In this case, I recommend going with nodpi type, because it includes all the resources available to cover the gamut of DPIs out there. So why don't we choose this one regardless? Because of the file size — because it contains resources to work on any DPI basically, it's a much larger file. If you can find one that matches your device's DPI perfectly, always go with it. Otherwise, you can also choose one that's a little higher and good. In our test case, however, I am not convinced that the 480 DPI version will look as good as downloading nodpi from the phone's 560 DPI. In that case, the larger file size is worth the tradeoff. Learning your device ins and outs is very simple. And luckily once you discover this information once you shouldn't worry about it again until you have a new phone. Phone.
