Home>About>Guidelines>Patients>Guideline Developers>Contact>Guidelines and Recommendations included in this section reflect existing evidence-based guidelines prepared by the Centers for Disease Control and Prevention and the Health Infection Control Advisory Committee. 2001 CDC Hemodialysis Recommendations 2016 Update 2001 CDC Hemodialysis Recommendations 2016 update review of current recommendations for infection prevention and dialysis control. Table 1 refers to current recommendations on specific topics contained in the 2001 document. Table 2 identifies topics not included in the 2001 document and presents the most recent CDC recommendations on the topic. Centers for Disease Control and Prevention 2016 Update 2001 Recommendations to Prevent Transmission in Chronic Hemodialysis Patients This paper, Centers for Disease Control and Prevention 2016 Update 2001 Recommendations to Prevent Transmission of Infections among patients with chronic hemodialysis update selected information and recommendations in 2001 Guide, Recommendations to Prevent Transmission of Patients Among Chronic Hemodialysis. This 2016 update contains new links/references to information, updated recommendations (table 1) and relevant CDC recommendations that were not addressed in the 2001 Guide (table 2). Some of the information and recommendations contained in the 2001 Guide have been dried up on the basis of information that led to the later recommendations of the CDC. These topics include: but not limited to: Testing for hepatitis C virus (HCV) testing for human immunodeficiency virus (HIV) Infection Standard Precautions in Health Care Settings Online 2001 Version (MMWR) Printed Version 2001 (MMWR) with pages pdf iconpdf image PDF - 386 KB Table 1: Information and recommendations in 2001 Guidelines, which were replaced later by CDC information and recommendations on the topic (Old Content) Infectious Control Topics to customize dialysis (sections and page numbers refer to the 2001 PDF Guide) (Updated Content) The latest CDC recommendations on the topic: Laboratory testing for hepatitis C virus (HCV) Infection Sections: - Screening and Diagnostic Tests (p. 11) - Regular Serological Testing (p. 24) Subject: Testing at HCV Infection Recommendations (MMWR 2013): Testing for HCV Infection : Update Guide for Clinicians and Laboratorians pdf icon PDF - 256 KB Theme : Laboratory Testing for Human Immunodeficiency Virus (HIV) Infection Section: - Viral Human Immunodeficiency Infection (p. 12) Theme: Laboratory Testing for HIV Diagnosis Recommendations (CDC/NCHHSTP 2014): Laboratory Testing for HIV Diagnosis - Updated Topic HIV test indications in patients Section: - HIV Prevention and Management (p. 29) Topic: HIV testing of patients in health care Settings Recommendations (MMWR 2006): Revised recommendations for HIV testing for adults, Adolescent and Pregnant Women in Health Care Theme: Cleaning and Disinfection Equipment and Environmental Surfaces Sections: - Equipment, Materials and Environmental Surfaces (p. 15) - Cleaning and Disinfection (p. 22) Theme: Cleaning and Disinfection Equipment and Environment : Guide to Disinfection and Sterilization in Medical Facilities , 2008 pdf icon PDF - 948 KB Theme: Standard Precautions to Prevent Transmission of Infectious Agents Sections: - Infectious Control Precautions for Outpatient Hemodialysis Settings Compared to Inpatient Hospital Settings (p. 17) - Infectious Control Precautions for All Patients (p. 19) - Cleaning and disinfection (p. 22) Follow the journey of two patients on dialysis who feel empowered to speak! Update: Additional guidelines and recommendations not included in the current guide. Preventing intravascular infections associated with catheter Screening for covert TB vaccination and immunization for patients and medical staff ACIP Vaccine Recommendations (ACIP 2016) The Company has created solutions for each focus area, including the ARM dialyther recycling system. And for patient care, two specific products prove popular wherever skin antiseptics is required, ExSept Plus is used, and Alcavis 50 is used when disinfecting catheter compounds. Both products are patented sodium hypochlorite solution, he adds. These products have been shown to be compatible with silicone and polyurethane materials such as Carbotane® and Tecoflex®. This is important when in contact with catheter materials commonly used in dialysis. The use of the wrong solution on the catheter can lead to the degradation of the catheter and possibly the violation of the catheter itself, which can

be fatal. For hand antiseptics, there are two alcohol-containing antiseptics, Aniosgel Plus, colorless and without perfume and Manugel 85 with color and perfume, with efficiency in 30 seconds to 99.999 percent (5 1 journal) reduction of bacterial col. disinfection equipment includes hydraulic pathway dialysis apparatus and liquid pathway clinic. There are several chemicals available to disinfect them, including the Alcavis 100, for disinfecting dialysis machines and fluid clinics way. The new product is Alcavis bleach Wipe. Available in dilution of 1:100 to destroy the surface of dialysis machines and dialysis chairs, the product also comes in a double package that has two towels, one for the machine and a separate for the dialysis chair, corresponding to the policies and procedures of the clinic. We also offer the EPA Wipe the bleach by 1:10 dilution of household bleach, bleach, Continues. It's perfect for blood spills and high-risk areas. Bleacher is the most regularly used external surface disinfectant at a concentration of 1 percent, says Chris Gustilo, Marketing Manager for Minntech Renal Systems. It is used on patients' chairs, dialysis surfaces including touch screens, scales, counters, etc. Ten percent bleach is also used, but usually only for blood shedding. Some products are specific for infection control in the dialysis market. These can include coating CVCs, antibacterial soap for pre-cleaning patient canulation, well-fitting visors, clothing barriers, sharp containers that prevent stick injury regurgitation, retractable fistula needles, medicine needles and syringes, disposable medication vials, says Padovan. Dialyzer re-practiced at about 50 percent of clinics in the U.S., Gustilo said. Renaline 100 (perathetic acid) is the most common disinfectant/sterile used. Almost all recycling is done on automated systems such as the Renatron II Dialyzer Reprocessing System. For fistulas, safety fistulas are increasingly used. The most common devices are made by Nipro, Medisystems and JMS. For antiseptics chlorhexidine is used very sparingly. ExSept Plus is used for some catheters. Alcohol and Iodine PVP remain the most commonly used disinfectants. Various access site holders have been developed for the hemostasis device after treatment. One of the new uses is the Super Stopper with a fistula clamp and ultra-clutch lid. For the blood tube, the industry is moving towards needleless injecting ports to prevent needle injuries. In addition, dialysis centers are looking at reducing the need for transducer protectors to reduce cross-consumption. Heat and chemical (i.e. PAA and bleach) are common methods for dialysis and water delivery systems. Water systems also use ozone. The rules continue to move towards stricter levels of endotoxins and bacteria. New and innovative products have been added to the market to make the environment safer for both patients and staff. These include Minntech's auto-division systems; This product is used to make dilution solution for disinfectants. Almost all companies use heat disinfection for water and delivery systems, Gustilo adds. Security fist needles are no longer on the periphery, and are now the norm. And the prevention of methicillin-resistant Staphylococcus aureus infection (MRSA) is becoming more frontal and central due to its effects on patients and their treatment. As can help Us know that the best patient care comes from collaboration between health care providers (nurses, doctors and technicians) and industry to identify the right products to protect the patient, Mishkin's muse. Padovan agrees, adding that sales and clinical specialists can ensure that the customer's client a strong knowledge base about the products and services they provide. Written and audiovisual educational materials should be used as a supplement to on-site learning. Subsequent and refreshing sessions will encourage product compliance and the capture of new employees. The CDC and Kidney Diseases (KDO-I) performance guidelines provide a framework for institutions to be found in good care. Most of these principles are evidence-based and valid. Proper training on the use of infection control products is also important, Mishkin adds. For example, there is a wide range of contact times required depending on the type of antiseptic or disinfectant used. Povidone iodine can take three to five minutes to be effective. Alcavis products instruct a total of two minutes of contact time. The user should know the required contact time of the solution they use to minimize the risk of infection. Again, one area of concern is that the solution can be used on what type of catheters. Alcohol and alcohol-based products are compatible with silicone, but Iodine is not. Conversely, iodine is compatible with polyurethane catheters, but alcohol is not. Manufacturers and distributors are playing an increasingly important role in the industry because they can develop and supply tools and chemicals that not only get the job done, but are also easy and quick to use, Gustilo points out. The more frequent patient ratio and staff turnover means that the tools they use should be easily studied. And the introduction of these devices is also a role for them, because, as Gustilo says, as the study shows after the study, the problem is not that the product has not been identified, which will help the clinics, but that the introduction of this technology in the long term does not occur. Cost efficiency is another important factor for manufacturers to focus on. Carlson notes that there are always cost problems affecting the dialysis market. The dialysis industry has been under Medicare control for more than 20 years for everything but drugs. In real terms, there has been a reduction in redress over the past 20 years. This, combined with mass consolidation (and concentration), has led to stifling innovation in the industry. One result of these cost limits is that the only innovations that are being adopted are those that save costs in a very short period of time. While innovation continues to occur in dialysis, these innovations take place outside the United States, where reimbursement is not so limited, he explains. specifically is a problem. The current Medicare reimbursement system, Part A and Part B, creates financial incentives for dialysis clinics to prevent infections, Carlson adds. Since the dialysis clinic does not receive a salary for managing the patient, the only consequence is when the patient is patient lost income for dialysis treatment. So if a patient misses three days of treatment a year (due to an infection related to the incident), then the total missed income is about \$900 (or \$300 per day). With the cost of treatment about \$250, the total profit missed is \$150. Thus, from a simple economic point of view, a dialysis clinic will be willing to spend up to \$150 a year on infection control and no more, which works up to about \$1 per treatment (\$150/153 a year). And that \$150 will be required to mediate all the mechanisms of infection. The ratio of staff to patients is another problem. If you visited dialysis units 20 years ago, the staff-to-inpatient ratio was one licensed employee (RN or LPN) to two or three patients. Today, most of the staff are unlicensed and une certified, and often there is only one licensed staff working on treatment sites in one shift. The overall staff-to-patient ratio currently ranges from one caregiver to four patients, Carlson continues. And the turnover of shifts is another problem. The dialysis clinic will have three to five shifts of patients per day. Patients are treated for four hours. The turnover between the patient's appointment and the start of the next patient is approximately 30 minutes. In this 30-minute period, the following steps should occur: (1) the outgoing patient has stabilized, (2) the area is cleaned and disinfected, (3) the dialysis delivery system is configured and adjusted for the next patient, and (4) the next patient sits. If the staff-to-patient ratio is so limited, setting all these steps between patients can be a challenge. Some of the necessary procedures at every turn may be short. And with staff turnover as an additional problem of overall staff turnover, especially with unlicensed and uncertified staff quite high in dialysis clinics there is a constant burden of education on staff regarding infection control practices, Carlson adds. By co-eating up with manufacturers and suppliers, dialysis providers can ensure that they give their best effort to comfort and care for their patients, to make their stay at the centers as fast and untroudful as possible, and to ensuring that costs do not negate the education and control of staff infections that are so critical to the patients they treat every day.
