Each question has only one correct answer, but quite often, it will be the answer as all options are correct or no option is correct. It is useful to know the basic formulas of volume, pressure, acceleration and moment by heart. In most cases, you won't need to do math, but you will need to understand the potential consequences of different forces. The first thing you should ask yourself while reading each question is what the mechanical principle of this question focuses on. The answer should be as accurate as possible. For example, do not respond to pulleys, and the number of ropes, pulling weight in the pulley system. If you are caught up with the question and you are not sure of the correct answer, try to exaggerate the use of force. For example, if a question compares two different heights, instead of fairly similar heights, think of the problem as if one point is very high and the other is very low. The same goes for distances (very short and very long), mass (very heavy and very light), and many other functions such as speed, volume, surface area, and force applied. This exaggeration will usually help you to clarify the essence of the mechanical principle that you should study. Location test: Mechanical fitness tests are usually given at the employer's office.
