Android Nougat has made some significant changes to the way notifications have been processed in an attempt to make them easier to digest. Android O takes another step forward with two new additions: delayed notifications and notification channels. Notifications are deferred In previous versions of Android when you brushed off the notification it's gone forever. That's ok most of the time, but there are times when we just don't want to notice right now, but anytime soon. Android O solves this problem with a snooze feature that temporarily removes the notification before restoring it later at the same priority level. In the state bar, when you swipe the notice aside (only slightly), you will be given the option to postpone it for 15 minutes, 30 minutes or an hour; Click any of them to defer this notice for a specified time. This will no doubt become a much-loved feature in the future, see it for about 40 seconds in our Android O first look video below. Notification notification channels allow developers to group their app's notifications by category. They are pre-defined, users can't choose their own categories, but they can choose how the categories behave. For example, Google says that messaging app developers can allow users to have a notification channel for each group chat they are a part of so they can disable certain chats from which they don't want to receive notifications from other users. Many apps already provide options for individual notifications, such as twitter allowing you to set preferences for tweets, retweets, likes, mentions, etc. (see image above left). However, it's only settings on or off that fall under the comprehensive Twitter notification profile that you've assigned in android settings (above right). Notification channels give developers, and then consumers, more control over individual app notifications: they no longer have to be defined by the app's settings, but instead by the notification channel settings. Google says that the following characteristics can be applied to notification channels, and that when a user assigns one of them, it will be applied across the channel. ImportanceSoundLightsVibrationShow on theoverride lock screen doesn't botherOnce again, it's up to the developer to implement notification channels to their app, which is not a requirement. It's worth greatly improving the user experience if they use it though. What do you think of these event notifications? Let us know in the comments. One of the best features of Android is its notification system. It uses the best ideas from companies that originally got it right, like Palm and Nokia, and then mixes them into display and the rich content that we've all come to rely on. Because the notification system is very very For a portable device that should keep you in touch with the outside world, it is also constantly improving. Android Pie is no exception. Android notifications are improving every year. That's what happened to Android Oreo. New look Your notifications can (and often do) look very different depending on which company made your phone. It's also part of the Android notifications - they're customized by developers who have built Android themselves, as well as app developers who know better what notifications their apps need to generate. Phones from manufacturers that tend to follow the example of Google like Motorola and Sony, all will be softer, rounder, and more colorful with Android Pie. Gone are things like grey lines to act as separators, and instead your status bar - which also has a new look to accommodate display cutouts - won't become part of the shadows when it's drawn. Instead, the hue turns into a map interface with round corners and bright icons for quick settings, and a second card for the actual contents of the notification. Bright colors and round corners will be subject to individual tastes (and discussions), but it's obvious that someone at Google has spent a lot of time and attention to detail here. The change looks more radical than it is, and it's probably a design, too. The shade of Android notifications doesn't need to be rebuilt or changed too much right away. That's how you're going to ruin a good thing. Instead, time should be spent to find the perfect interface to show us what we expect to see. Android is ripe. Smart everywhere smart answers using Google's machine learning algorithms come standard with Android Pie. The phone analyzes the contents of the message when it shows a preview in the notification, and as a result you are given three smart answers that you can send at the touch of a button. They were supported with Android 8.0, but now Google is building them into a notification system for all app developers to use. You can of course choose to ignore the offers and enter your own response directly from the notification if you like. And you may well be able to use shadow notifications without opening a messaging app. The pie brings changes that identify the sender and display the last few lines of conversation at the top of the phone. The new Person class can get user data from your contacts and show avatars, aliases and other information about who is talking. It even works for group messages. If you want to answer, there is no need to open the app. Everything you need is available at the bottom of the shadow, including things like saving as a draft, marking how to read, delete and respond just like the answer box in itself For those of us who are eager to send short and sweet messages, it's like having a second miniature version of the app in your notifications. Just what you want to see pie brings much better control control fine-tuning notifications. You've always been able to stop the app from notifying you completely, but as the Android notification system gets better, tools such as selecting the type of notifications you see from the app improve, too. Anytime you get a notification you can push it long and then click the information icon in the top right direction. This will take you to the app settings page, which you can also get through device settings in apps or apps and notifications, depending on what type of phone you have. Once on the app settings page, click on the notification list and you'll have control over what categories of notifications you want to see and how you want to receive notifications. Goodbye, Mr. Annoying with Android Pie, APP_NAME uses a battery message that is bugged by so many users now oyle in the past. You can still look at using the battery through the settings if you need to do so, but seeing that YouTube uses the battery because it hasn't been closed by the system won't haunt you anymore.

Shhh! Don't Bother has once again been tweaked with android pie. Now you can change the Do Not Disturb settings in a way that makes sense. Long-pressed Fast Settings icon doesn't bother gives you the ability to switch what gets muted, exceptions to general rules, and graph when not to bother is automatically turned on. We're not sure how manufacturers will make changes here, but it's nice to see bare-bones Android have a little more control over what is an important feature for many of us. Notifications of Importance Notifications are one of Android's long-standing strengths. Google always makes improvements when the new version of Android rolls, and with Android Pie they have done a great job. We can't wait to see what our favorite developers can do with these new tools! Updated September 2018: Android 9 Pie is officially out! We went through the settings and checked all the goodies. Finally, Google has added quick settings for the retractable notification in Android 4.2. This is a feature that many have wanted in the Android warehouse since, well, forever. Enthusiast ROM added them. Manufacturers added them. You can download apps that add them. And now, Google has added them to the latest version of Jelly Bean. Only, Google did it differently. While quick settings usually serve as switches in the retractable notification, Google has gone the other way. Crazy, or crazy as a fox? Let's see. The bottom line is that pull down the bar notifications and you see your notifications as always. Only where before there was a Button Settings now ... something else. The icon shows the person, with five sketches below and from him. This is actually a preview of what's to come. Click this button, and the notification section will turn over to quick settings. (And the icon on the top right to the right of the screen switches Fast Settings icon back to notification icon.) Settings listed: Your Google profile: If you join Google, your name and profile picture will appear. Click on it and you're asked if you want to view your Google profile. (Don't know why I ever want to get to my G profile that fast, but chances are Google will tweak that at some point.) Brightness: Click on this and you'll get a small pop-up that lets you adjust the brightness of the display. This is different (and better) than a full-screen brightness notification. I use this a lot already. Settings: here it is. A short way to a full settings menu. Wi-Fi: Shows its own network. Tap and it will take you to the Wi-Fi settings. Mobile data: Shows what media you are on and the power of the signal (in the bars). Battery: There is a visual indicator and percentage. (FTW numbers!) Click and you'll get a battery section in the Settings menu. Airplane mode: Turns off the radios when you're on the plane. (Or if you want to pretend you're on a plane.) Bluetooth: Takes you to the Bluetooth Settings menu. (Fast settings will show if on, turn off if turned off.) Wireless display: Available in quick settings when display settings are turned on. One finger for notifications, two for settings That's a really cool part - Google gave a way to quickly access the quick side of the setup for tightening. Here's how it works. Pull down from the top of the screen with one finger and you get the notification area. Pull down with two fingers and you immediately get a quick tweak. Presumably, this will work just fine on all smartphones. (Restless in us, however, a little concerned about the strange touch panels behaving strangely, but we'll cross this bridge when we get to it.) In practice, we got the hang on two-finger napkins just fine, although we're not quite 100 percent in practice. Most of the time it works, sometimes it's not. Chalk that up to the pre-release software, perhaps, or (rather) an operator error. Oh, and one thing we'd like to see added - when you have quick settings open, you can't come down from above to get notifications. You will have to press the button in the top right to flip back. It's not as fun (or fast) if you're holding your phone in your left hand. Fast Settings and Tablet Things are pretty much the same on tablets in Android 4.2. You have the same quick-setting buttons - with automatic rotation replaced here with the cellular button. (Presumably, the mobile button will remain on any tablet that has a data connection.) Another difference for tablets is how you access notifications and quick settings You still drag from the top of the display (in portrait or landscape orientation). But notifications are on the left, and quick settings on the right. There's not one, not two fingers. (And you can't complete both down at the same time. we'll shop that picture for example.) It is not yet known whether apps will be able to add items to the notification menu or how they will be able to do so without breaking the iconography. There is no way to add or remove settings at this time. Be that as it may, quick settings are a welcome addition to Android 4.2, and Google has implemented them in a smart way.
