End of the line! End of the line! It's never easy to pick the best out of something. This, of course, is almost never fair. But it breaks because it's our job to use and experience all things and to help tell our stories. That's why we bring you all the best. The best android phones. The best pills. The best accessories for your devices. The best smart home gadgets. The best apps to play and work with and do whatever you want to do. These are the best of the best. Android 4.1 may be on Google Nexus 7, but it's too early to appear in Android History data you can browse by browsing Android developer numbers and watching in each release as the latest Android build slowly starts to get traction and old builds start to fade. We've seen Froyo (Android 2.2) move from a small fraction of Android models to a dominant build. We watched as the gingerbread replaced Froyo. Now, this Ice Cream Sandwich has begun a journey from new upstarts to eventually running on the vast majority of Android phones. It's too early for Jelly Bean (Android 4.1) to register. The latest figures show that between Android 4.0 and 4.0.4, Ice Cream Sandwich is set on 10.9% of Android devices. That's a far cry from 64% using gingerbread, but the launch of the Samsung Galaxy S III is only going to shake things up in favor of an ice cream sandwich. 27.3% are still sporting Android 2.2. Froyo. The information, by the way, uses data collected for the two weeks ended July 2. Believe it or not, 4.7% of active Android devices run Eclair (Android 2.1), while a combined 0.7% use devices running Android 1.5 and 1.6. How many Nuvifones are still in use? Source: Androiddevelopers via AndroidCentral Last Breakdown of Android SUBSCRIBE Or To our NEWSLETTER! 5 ways the G1 is better than the iPhone 5 Reason the iPhone is still number one. G1's Not a Real Media Player ... However, the iPhone isn't just video playback - it's one of the best (and best) portable media players on the market. While we will certainly see developers making video playback programs for the G1, there are none built into it. But Apple beware: If there's one thing the open source community likes, it's support for a wide range of video formats and codecs. All this will take one reliable mobile playback program (mobile VLC, perchance?) to make users remember how much they hate converting videos into MP4 so they will play on the iPhone. 2. The iPhone's thinner G1's slide-out keyboard may be useful, but it comes at a price: the G1 brings us back to the pocket bulging smartphones of yesteryear, while the iPhone is slender enough to fit in the front pocket of your Levis. 3. No Multitouch G1 uses a capacitive touchscreen. It's the same very type of screen found on the iPhone (most (most The phones use mostly lower resistive touch screens), and should allow the G1 to compete when it comes to sensory sensitivity. But the G1 doesn't have the ability to multitouch the iPhone. While the G1 tries to make its score by using long touches to bring up deep menus, it loses on the huge amount of functionality (and coolness) that comes from the iPhone's ability to feel two fingers at once. 4. Jack's Terrible Headphones iPhone proved that people were willing to listen to music on their mobile phones. However, most manufacturers are reluctant to put the standard 3.5mm headphone jack on their phones, forcing customers to instead use bulky adapters or subpar-bundled headphones. The 3G iPhone bucked this trend (the original was an annoying drowned headphone jack that can only take specially made headphones), but the G1 relies on an annoying own plug. To make things work, early signs that adapters won't even be available when the phone first hits the shelves, making bundled headphones the only choice. 5. The iPhone's internal memory currently comes in 8GB and 16GB varieties, and we'll probably see a 32GB version soon. The G1 only has 192MB of onboard memory, and comes with a 1GB micro-SD card. It's not exactly enough memory for a phone that should be full of music and downloaded apps. If you want an 8GB G1, you'll have to purchase an 8GB micro-SD card, which will push the price of the phone from \$179 above the iPhone's \$199 price tag. If T-Mobile, Google and HTC really expect us to use the G1 as a mobile computer, they should give us more memory.
