After understanding that it's a vector, let's learn to add and subtract the vector. Adding and subtracting vector quantities does not follow simple arithrthm rules. A specific set of rules are followed to add and subtract vectors. The following are pointed to some points while adding vectors:Now, talking about subtracting the vector, it is the same as adding the negatives of the vector to subtract. For a better understanding, let's look at the example given below. Let's consider the two vectors

A
→

{\displaystyle {\overrightarrow {A}}}

 and

B
→

{\displaystyle {\overrightarrow {B}}}

 as shown in the figure below. We were required to subtract

B
→

{\displaystyle {\overrightarrow {B}}}

 from

A
→

{\displaystyle {\overrightarrow {A}}}

. This is just the same as adding

B
→

{\displaystyle {\overrightarrow {B}}}

 and

A
→

{\displaystyle {\overrightarrow {A}}}

. The result is shown in the figure below for vector quantity usually, an arrow on top such as

v
→

{\displaystyle {\overrightarrow {v}}}

 is used, which indicates the value of the *v*/vese vector, and also explains that the quantity has both magnitude as well as direction. Q1: According to the following is a list of quantities. Each quantity is categorized as vector or scalar. 20°C 5 mi., North 256 bytes 5 m 30 m/s, East 4000 calories Response: 20 degrees Celsius scalar 5 mi., North Vector 256 byte scalar 5 m scalar 30 m/s, East Vector 4000 calories Scalar Q2: Ashwin walks 10 meters north, 12 meters east, 3 meters west and 5 meters south and then stops to drink water. How much is the magnitude of his movement from his original point? A: We know that displacement is a vector quantity, so the direction in which Ashwin walks or along a axis will be positive or negative. Now to find the entire distance that has traveled along the y axis, let's consider moving north positively and moving south as negative.

(
∑

y
=
10
,
m
−
5
,
m
=
5
,
m
)

{\displaystyle (\sum y=10,m-5,m=5,m)}

 He moved a 5-meter note north along the y axis. Likewise, let's consider his move east as positive and the move west negatively.

(
∑

x
=
−
3
,
m
+
12
,
m
=
9
,
m
)

{\displaystyle (\sum x=-3,m+12,m=9,m)}

 He moved a note 9 m east. Using Pythagoras theory, the resulting displacement can be found as follows:

(

D

′

2

=
(
∑

x

′

2

)
+
(
∑

y

′

2

)

)

{\displaystyle (D'^{2}=(\sum x'^{2})+(\sum y'^{2}))}

 Replace values, we get

(

D

′

2

=
(
9

′

2

)
+
(
5

′

2

)

)

{\displaystyle (D'^{2}=(9^{2})+(5^{2}))}

(

D

′

2

=
(
106

′

2

)

)

{\displaystyle (D'^{2}=\sqrt{(106)^{2})}

 (D=10.30,m) Q3. What is the magnitude of a single vector? A: Magnitude is a single vector of unity. A single vector has no unit or dimensions. To know more about what a vector is, in addition to vector and subtract, stay tuned with BYJU's. Also, sign up to BYJU's – learning program for interactive loads, engaging videos related to physics and unlimited academic help. Scalar products and vector products are two different vectors that are most commonly used in physics and astronomy. The scalar product is two vectors As a product of the magnitudes of the two vectors and cosine, the angles between them are. Scalar is the product of scalar products can be found by taking the component of one vector in the direction of the other vector and multiplying it with the magnitude of the other vector. Can be defined: The scalar product or point product is an algebraic operation that takes two sequences of numbers with an equal length and returns a single number. This can be shown as follows: scalar product

(
vec
A
)
⋅
(
vec
B
)
=
A
B
cos
⁡
(
θ
)

{\displaystyle (\vec {A})\cdot {\vec {B}}=AB\cos \theta }

 where

(
vec
A
)

{\displaystyle {\vec {A}}}

 represents the vector

(
vec
A
)

{\displaystyle {\vec {A}}}

 represents the magnitude of the vector

(
vec
A
)

{\displaystyle {\vec {A}}}

 the scalar product is also referred to as the point product or the internal product, and remember that the scalar multiplication is always determined by a point. If the same vectors are expressed as unit vectors i, j and k along the x, y and z axis respectively, the scalar product can be stated as follows:

(
vec
A
)
⋅
(
vec
B
)
=

A

x

B

x

+

A

y

B

y

+

A

z

B

z

{\displaystyle {\vec {A}}\cdot {\vec {B}}=A_{x}B_{x}+A_{y}B_{y}+A_{z}B_{z}}

Where,

(
vec
A
)
=

A

x

i
+

A

y

j
+

A

z

k

{\displaystyle {\vec {A}}=A_{x}{\vec {i}}+A_{y}{\vec {j}}+A_{z}{\vec {k}}}

(
vec
B
)
=

B

x

i
+

B

y

j
+

B

z

k

{\displaystyle {\vec {B}}=B_{x}{\vec {i}}+B_{y}{\vec {j}}+B_{z}{\vec {k}}}

matrix) Scalar products are useful for showing vectors as a row matrix or column, rather than as high unit vectors. If we treat vectors as column matrices of our x, y and z components, then the transposes of these vectors will be row matrices. Therefore, the vectors

(
vec
A
)

{\displaystyle {\vec {A}}}

 and

(
vec
B
)

{\displaystyle {\vec {B}}}

 are similar to:

(
vec

A

T

)
=

A

x

A

y

A

z

{\displaystyle {\vec {A^{T}}}=A_{X}\ &A_{Y}\ &A_{Z}}

(
vec
B
)
=

B

x

B

y

B

z

{\displaystyle {\vec {B}}=B_{X}\ &B_{Y}\ &B_{Z}}

matrix) The matrix product of these 2 scalar product matrix will be given 2 matrix, the sum of the space components corresponding to the two vectors given, the resulting number of the scalar product will be vector A and vector B.

(
begin{matrix}

A

x

A

y

A

z

\end{matrix}
)
(
begin{matrix}

B

+

A

y

B

y

+

A

z

B

z

{\displaystyle {\begin{matrix} B_{X}\ B_{Y}\ B_{Z}\ \end{matrix}}{\begin{matrix} B_{X}\ B_{Y}\ B_{Z}\ \end{matrix}}=A_{XB_{X}+A_{YB_{Y}+A_{ZB_{Z}}}{\vec {A}}\cdot {\vec {B}})}

 the product of the large vector vector of two given vectors can be found by taking into account the product of vector magnitudes equal to the angle between them. Can be defined: The vector product or cross product is a binary operation on two vectors in the 3D space, the magnitude of the vector product can be shown as follows:

(
vec
A
)
×
(
vec
B
)
=
A
B
sin
⁡
(
θ
)

{\displaystyle {\vec {A}}\times {\vec {B}}=AB\sin \theta }

 Remember the above equation is only for large, the following expression is used for the direction of the vector product,

(
vec
A
)
×
(
vec
B
)
=

(

A

y

B

z

−

A

z

B

y

)

i
+
(

A

z

B

x

−

A

x

B

z

)

j
+
(

A

x

B

y

−

A

y

B

x

)

k

{\displaystyle {\vec {A}}\times {\vec {B}}={\begin{matrix} \vec {i} & \vec {j} & \vec {k} \\ A_{X}&A_{Y} &A_{Z} \\ \vec {B}_{X}&\vec {B}_{Y} &\vec {B}_{Z} \end{matrix}}

 [The above equation gives us the direction of the vector product] the vector products shown by Determinants

(
vec
A
)
×
(
vec
B
)
=

(

A

y

B

z

−

A

z

B

y

)

i
+
(

A

z

B

x

−

A

x

B

z

)

j
+
(

A

x

B

y

−

A

y

B

x

)

k

{\displaystyle {\vec {A}}\times {\vec {B}}={\begin{matrix} \vec {i} & \vec {j} & \vec {k} \\ A_{X}&A_{Y} &A_{Z} \\ \vec {B}_{X}&\vec {B}_{Y} &\vec {B}_{Z} \end{matrix}}

 Now the above determinant can be solved as follows:

(
vec
A
)
×
(
vec
B
)
=

(

A

y

B

z

−

A

z

B

y

)

z

B

x

−

A

x

B

z

)

j
+
(

A

x

B

y

−

A

y

B

x

)

k

{\displaystyle {\vec {A}}\times {\vec {B}}={\begin{matrix} A_{Y}B_{Z}-A_{Z}B_{Y} \\ A_{Z}B_{X}-A_{X}B_{Z} \\ A_{X}B_{Y}-A_{Y}B_{X} \end{matrix}}

 Scalar application Vector products are countless especially in situations where there are two forces that act on one body in another direction. Example: Calculation of magnetic force that operates on a moving load in a magnetic field, other applications include determining net force on a body. Refer to the note on the prelinear algebra about the perception of the point product. Suppose that w vector projects on vector v.Notation:Scalar projection: Componentvw, read as Component of w onto v. Vector layout: Projectionvw, read as plan w on v. Note that: When you read it, it is in reverse order! It's very important! Projection formula is noted that, the formula concerns these concepts as a requirement:Product point calculates vectorUnit cosine product how to calculate scalar projectionThe name is just the same with the names listed above: increase. Refer to a lecture by Imperial College London: ProjectionRefer also to Khan Academy: Introduction to ProjectionsWhat if we know vectors, and we want to know how much scalar designs (shadows)? Example: How we're going to solve this is this: we know vectors, so we can get them point by considering their linear composition, and we know the length of each vector, using the Pythagorean theory; How to calculate vector predictions is another idea for the layout, and less intuitive. Remember that the scalar layout is the length of the projected vector on the other vector. And when we add direction on length, it becomes a vector, which lies on another vector. It then makes it into a sampling scheme. This can be understood as this formula:But usually we write it as this:Refers to the video for the formula by Kate Penner: Vector Designs EquationsRefer to video by Firefly Lecture: Vector Prediction — Example 1Example:- Replacing our values in our formula, we get

(
vec
a
)
⋅
(
vec
b
)
=
2
⋅
4
⋅
cos
⁡
(
2
)

{\displaystyle {\overrightarrow {a}}\cdot {\vec {b}}=2\cdot 4\cdot \cos (2)}

So, large vector

a
×
b

{\displaystyle {\overrightarrow {a}}\times {\vec {b}}={\overrightarrow {27.65}}}

Asked by wiki-user this lecture, the web version of the third lecture given in the electromagnetic theory paper of the class of physics honors degrees, was delivered on January 9th, 2018. All the electromagnetic theory lectures in this series will be found here. It's an insect repellent that works based on our understanding of electromagnetic wave. Color light of different types is an example of electromagnetic wave. They are governed by Maxwell's equations and their deeper framework is the subject of our discussion in this

speech. Topics covered by electrodynamic formalism - basic theory B. Use helmholtz theory - to electrostatic C. Application of Helmholtz theory - to the magnetostatic formalism of Helmholtz's electrodynamic theory in our previous lectures, lectures - me and lectures - second, we discuss Maxwell's equations in the open space and in material media. We also discussed border conditions that help us resolve and squares. Fields and fields are vector fields, and Maxwell's equations involve differentiating these vectors. So we have to deal with loops - and divergence - of these vectors - or vector fields, apart from any boundary conditions to be satisfied by this, as we saw in our last related speech. Theorems Helmholtz provides some useful relationships and properties that help us determine and unique contexts. It is important for us to understand mathematical strictness and provide the physical strength of these equations in having a unified formal treatment that all electrodynamic use. One requires a basic skill in the vector account to understand the inherent importance of these methods. To start with one can go through the slide here - vector account, to keep sensible on vector account concepts. There is a theory that deals with the implications of a vector's ring. Theorem 1 If curl of a vector field is zero — everywhere, then can be written as the gradient — of a scalar field, also known as the scalar potential function. Here's a sign minus just a convention. Ali. Such fields, - here, are known as less loop or irrotational fields. B. The ring is zero everywhere. c. Quantity is independent of the path - of integration, as long as the limits are fixed. d. Quantity for closed paths or merge loops. Ebrahim. The vector can be wrote as a gradient of some scalar in such a way that, . Fatemeh. If any of the above statements are valid, it validates all others. That implies and the like. G. Scalar's potential is not unique. Any function independent of the position can be added unchanged now there is a theory that deals with the divergence consequences of a vector. Theorem 2 If divergence — of a vector field is zero — everywhere, then can be expressed as the curl of a vector potential function. Ali. Such fields—here, are known as less divergence or solenoidal fields. B. Divergence everywhere is zero. le.. c. Quantity— independent of the level of integrity, as long as the surface boundary—a line, is constant. d. Quantity for the integration package level. Ebrahim. The vector can be wrote as a loop of some vectors, which, . Fatemeh. If any of the above statements are valid, it validates all others. That implies and the like. G. Vector potential is not unique because the gradients of each scalar function are less than the oven. Gradients of each scalar function can be added to the vector, and this conversion will left the vector unchanged. As one increases the new potential and old potential to the same. There is another mathematical result that has implications for both of the high mathematics and we will express it. Each overall vector, regardless of whether or not this vector is divergent-less, and whether or not this oven vector is less or not, can always be written as a sum of two vectors, a. A. A vector that loops some vector and b. is another vector that divergences some of the scalar function. in symbols: . The application of the above theories to our 3 positions will study how the above theories largely signify for almost all areas of electromagnetic theory. The furnishings together are known as Helm Holtz. But we studied them 3 positions - gradually moving up the ladder of totality, beginning with our familiar knowledge of static electric and magnetic fields. a. Electrostatic b. Magnetostatic and electrostatic electrostatic electrodynamic when electrical loads are constant, the resulting electric fields lead to electrostatic behavior. In these circumstances, electric fields—always irrotational, i.e. curl-less, thus satisfy the conditions—theorem 1, of helmholtz theory. Because all other conditions are satisfied and a potential function known as scalar potential can be defined. Here's Ref - For reference, the lower limit of the integral sign stands for a particularly selected place for potential, from where all the calculations are made. There Two standards for implementing this idea; If load distributions are limited, other means of calculating E.g. are supposed to be explored. One should not be set to a lower level of integration, rather than Ref, for an infinitely long cylinder. The above box equation, which we can define because the electrostatic field ring is zero, is an integral form of scalar potential. The di dicial shape is the definition of the potential of the scalar after that; Two Maxwell equations—one vector and one scalar, and a total of four equations, increase the Poisson equation, Poisson equation: When the term source is absent, the Poisson equation is converted to the Laplace equation. Laja equation: The potential can now be calculated as: where it is known as the separation vector. Now the electric field can be calculated from the phrase is nothing but the law of Columb. Magnetostatic problems follow the same logic. Magnetostatic nature is defined by constant currents or constant currents. That means the load densities that produce the field should not vary in time. Math: . When used in the equation of continuity: , this means: . In this way, the magnetostatic condition is given by: . Maxwell's second equation is: magnetic fields are low divergence in all situations. According to the 2 theory of helm holtz afterwards, magnetic field can always be written as loops of vector potential, as.. It is known as vector potential or magnetic vector potential. According to the Amp Rule of Maxwell Equations — that is, we have: . We have already discussed that magnetic vector potential is not unique. Because the gradient of each scalar is less than the oven. with this freedom , we can always find scalar , so that . If the potential of the main vector is not less divergence we can add to it, as it is without less divergence. so , and . for us . This is nothing but the Poisson equation, as we have seen. Remember the Poisson equation for electrostatic: . So it acts like a source: . As is the case with electrostatics if we have a solution for the Poisson equation: . This solution is given by: . If the term source does not go to zero, (in) we should use other devices such as the electrostatic case. It is always possible to find, to divergence less. In this way, the rule is amp: . This is the Poisson equation—in fact, three Poisson equations, because it's a sampling equation. If the solution is this: So for our constant flows: We discuss the 3rd status of usable Helm Holtz issues General case of electrodynamic in the next lecture, - speech - IV. Fourth.
