(Aircraft Seat Command) | Write an app that can be used to allocate seats for a commercial aircraft. The plane has 13 rows, with six seats in each row. Rows 1 and 2 are first class, rows 3 to 7 are business class, and rows 8 to 13 are economy class. Use two parallel arrays: a one-dimensional array to store the row number of the seats (Row #) a two-dimensional array of 13 rows and 6 columns to the seat assignments (*) and save seat letters (A-F) Your app should prompt the user to enter the user to import Next information: Retain a seat (Yes (Y/y) or No (N/n)) Assign ticket type (first class (F/f), business class (B/b), or economy class (E/e)) Select desired seating (1-13 and A-F) A-F) app must contain at least the following features: a function to initialize the seating plan. a function to assign and select the desired seat. a function for each ticket type that determines whether a seat is occupied and if that class is full. Execute the seating plan in the following form: Seating Plan Here, * indicates that the seat is occupied. Make it a menu-driven program; assing the user's choices and allows the user to make the appropriate choices. Airlines typically offer passengers a variety of travel classes to choose from. On short domestic flights, many airlines offer a two-cabin seat configuration, with a Business class and an Economy class. On longer transcontinental or international flights, airlines typically offer a three-cabin seating configuration. The three different seating cabins include Economics Class, Business Class and First Class. Higher seat classes, such as Business Class and First Class, are usually more expensive and offer travelers more space and usually takes up most of the seats on a plane. The Economy Class seating plan on a typical Boeing 747-400 consists of rows with three adjacent seats on the left side of the plane, four adjacent seats in the middle of the plane and three more adjacent seats on the right side of the plane. Seats in the middle of the plane and three more adjacent seats on the left side of the plane. Some airlines offer a Premium Economy Class. This travel class is more expensive than the usual Economy class and offers a slightly higher quality accommodation. Compared to the standard Economy Class seats are generally wider and have 6 inches more legroom. This class also offers larger custom televisions, better snack/beverage service and fully adjustable seats. In Business Class, seats have an average width of 21 inches and a pitch of 57 inches. Compared to economy class, there's nearly twice as much legroom and 3 to 4 inches of extra seat width. The Business Class seating plan on a typical Boeing 747-400 consists of rows with two adjacent seats on the left side of the plane, three adjacent seats in the middle of the plane and two more adjacent seats on the right side of the plane. Business Class travelers can expect to be accommodated with high-quality in-flight food and entertainment services. The First Class seating section is designed to be the most comfortable. This small cabin is usually above or below in front of an aircraft. First Class Seats Are 1 to 2 Inch Wider Than Business Class and has 10 to 30 inches more pitch. First Class travellers can expect best in-flight service from a higher flight attendant to passenger ratio. Better foods, in addition to wine and cocktails, are also served in First Class. Try form() send to getData() and pass row by copy rather than by reference. Inside getData() assign the actual seat number by converting input row number and column char to appropriate index numbers for the array. No need to throw anything I can think of. It will be the... Jump to Post Lerner 582 Almost a Post Maven 11 Years ago Try Sending Form() to getData() and pass drive by copy rather than by reference. Inside getData() assign the actual seat number by converting input row number and column char to appropriate index numbers for the array. No need to throw anything I can think of. This will complicate the getData() function a little, but simplify the print function. 11 years ago .. problem is after the app works the first time, then the user wants to do it again (which I used a while loop), for example, selecting row 1 B, the form will show X at row 1 B, but not the row 2 A (which was the first time the user chose) anymore... this is because int the function void printForm(char form[[6], int row, char column) you get in the block only once if (i == row - 1 & amp; j == static cast<int> (column)-65) You do not make the actual change in the char form[13][6]; Suppose in the elements of the 2D form[1]. You call this function at the beginning of your app itself, something like this: void Initialize (char next= you= modify= the function= void= printform(char= form[][6],= int= row,= char= column)= {= assign= the= seat= to= the= on= you= can= check= it= seat= is= already= filled= at:= if= (=> <int>(column)-65]== 'X') /{ cout <Seat already= assigned= .choose= another= seat;= return= = here= i= make= crude= assumption= that= the= user= enters= correct= data= ,i= mean= rows= and= columns= which= are possible= ones.= you= don't= check= that= the= seat= is= available;= => < endl;= cout=> < x= indicates= that= the= seat= is= putd.= => < endl;= cout = > < setw(12) = > < setw(12) = > < setw(6) = > < setw($j=\> \< 6;=j++)= \{= cout=\> \< right=\> \< right=\> \< setw(6)=\> \< form=[i][j];= \}= cout=\> \< endl; \} \}$ 11 Years Ago Thanks zalezog. I have changed my program according to your suggestion and it works endl;= $\}= \}= 11=$ years= ago= thanks= zalezog.= i= have= changed= my= program= according= to= your= suggestion= and= it= works=></ endl; } 11 Years Ago Thanks zalezog.
