How to set a Grandpa clock in rhythm and regulation to keep the correct time 508 videos Play all Noah Posner mechanisms: Ancient Watch Repair Course for Beginners How to Learn Clock Repair - Duration: 5:39. ... Watch Video Chain Drive: If your weights hang from the chains, then you will need to pull the chains (using a cloth or glove to avoid handling the brass chains directly) directly once a week to move the weights back to the top of the watch and start other weeks of running. Never lift the weight when pulling the chain! Contrary to popular opinion, this is not necessary or desired. (See my article on Clock Myths) It is best if the chains do not pull so far that the top of the weight hits the bottom of the mechanism or the plate of the seat on which it is set. If you do this you're stressing the chains and it may very well be damaging the top of the weight shells as well. It's best to stop with an inch or two to spare. Leaving some space here also allows for easy removal of weights in case the need arises. If you don't, you won't be able to remove the weights until it runs out a bit. This can be really inconvenient if your watch doesn't work after rolling. If you forget to roll the watch the weights will hit the bottom of the watch and the watch will stop. It's better if you don't let this happen. There is a chance to do so that the ringer or the clock strike will jam and it will be difficult to reset the clock. Always keep in mind when pulling chains that the pendulum is not far from the ascending weights. Hitting the pendulum with the weights on its way up can cause a problem and the cost of a call from potentially reset a beat or replace a broken suspension spring. Cable Drive: If your weights hang from pulleys it will be necessary to roll the watch using the crank that comes with it. Although it is possible to roll the watch with key, a crank is the preferred method. It is generally not possible to roll a watch too high or too tight, but as mentioned above, on weight-driven watches it is usually best not to go all the way to the top. Many of the most modern cable-operated watches will have a special set of gears (Geneva stops) that stop the winding process before there is any possibility of winding too much cable into the barrel inside. However, these limits are set only for movement and do not take into account different case styles. This means that the watch can still allow the weight shell to come into contact with part of the box itself. Again, we don't want the weight to add high enough to hit anything. When this happens we put too much tension in the cable and we will not be able to remove the weight if necessary. It is best to always leave the pulley exposed. Don't roll it up so high I can't really see the pulley. Special note: Most cable-operated watches do not allow weights to fall so far as to hit the bottom of the case. In many cases, the weights will stop up to 12-24 inches from the bottom. The important thing is not how far the weights go down, but whether the watch works for a week with or a single winding. What I do when I'm on vacation: The best thing I can do if you're not going to be home on the winding day is just stop the clock before you go out to keep the pendulum from swaying. Hand adjustment There are some basic rules regarding manual setup. These are: 1. Use only the hand of minutes. 2. Never move the hour hand by yourself to set the clock. 3. Never move your hand of minutes while the watch is ringing or tapping. The minute hand can be rotated in any direction; clockwise or counterclockwise. If you go clockwise it will be necessary to stop every quarter of an hour and let the clock sound before advancing to the next hour of the quarter of an hour. Yes, when you go ahead you hear the click in the quarter of an hour and the clock does not sound then it is OK to move on to the next quarter. Please note that depending on how well your watch fits the watch may not sound exactly in the quarter. It may be necessary to go a little further than it before hearing the click that releases the bell. If it goes counterclockwise, the watch will normally not sound, so there is no need to expect anything; just go back to the right time and its done. After moving your hands back you can hear the clock ring the wrong bell. If this happens, it means it is out of sync. For watches which I mean in this manual, the clock will resynchronize itself. He usually will do it in an hour. So, the next time the time change occurs, don't panic. When spring forward simply advance the hand of minutes clockwise, stopping in each trimester before moving on to the When we go back, move the minute hand back an hour. It's really that simple. Don't do what so many people do and move the hour hand forward or backward for an hour on its own. If you do this, the clock will dial badly until you put the time hand back on where it was. Regulation As nice and expensive as most Grandpa watches are are not perfectly accurate! This is true because they are temperature sensitive. What works accurately in the summer will normally not work accurately in the winter unless the temperature in your home never changes. Manufacturers know that this is a problem and that is why there is always a way to compensate for these changes by adjusting the length of the pendulum. The means of compensation is performed by using the regulatory nut normally located under the round brass disc at the bottom of the pendulum. Tightening the nut or turning it to the right raises the pendulum disc and will make the watch run faster. Loosening the nut to the left will lower the disc and slow down the clock. Generally speaking, a full turn will make a difference of approximately two minutes per day. Very specific italicized words in the previous sentence are crucial to understanding whether you want your watch to work as accurately as possible. First we're talking about a complete twist of the nut, not a turn of the finger. The next important word is approximately. It is impossible to reach a rule that will apply to all clocks so the phrase a turn equals approximately two minutes is a generalization or a starting point. Now we have to stress by day. For example, fourteen minutes of fasting per day is not the same as fourteen minutes of fasting per week. Fourteen minutes of fasting per week is only two minutes per day (14 minutes divided by 7 days equals two minutes per day). So, here's the process you need to follow. 1. Adjust your hands on the watch according to a watch you know is accurate. 2. Adjust your hands as accurately as possible. For example, there is a significant difference between nine and a half minutes after ten and nine minutes after ten. 3. Wait twenty-four hours. 4. Determine how fast or slow your watch is by comparing it to the same clock against which you set it. 5. With this information, perform the appropriate number of turns (according to the rule above) of the adjustment nut in the correct direction. Up accelerates it up, downwards slows it down. 6. Reset hands accurately (using the same watch again). 7. Wait another twenty-four hours. 8. Continue repeating the above process until you succeed. This will usually take several days to a week. After let the clock run for a while without a regular, you may notice that over time the clock has gained or lost a few minutes. It's important remember that the clock didn't do this overnight, but it took several days or more for a small difference to accumulate in that biggest gain or loss. You should divide this number of minutes off by s passing many days since you last set it and adjust accordingly. Once you have achieved success in regulating your watch you should remember that in a few months it is very good to have to regulate again. As the season changes, so will your heating or cooling patterns that in turn affect the accuracy of the watch. Changing the bells- Using the bell selector Your watch may or may not give you the ability to change the bell on your watch. Some play only the Westminster bell and cannot be changed. Many of the most expensive grandfather watches have what's called a Triple Chime. This simply means that the watch will play three different songs. If you have this feature then there is usually a lever protruding through a slot in the dial. 99% of the time this slot or lever will be close to number three. Some have the selection lever above number twelve or below number six. There are also some watches, usually more expensive that have a rotating dial (circular dial) for selecting and muting the doorbell. When those are present there are usually two of them towards the top of the sphere, one on the right and one on the left. Other watches have the lever for selecting bells inside the box and can only be reached by opening a side door or removing a panel. These levers are rarely marked. Marked.
