What is a wsd port
VSD is a port monitor instead of a port. WSD devices communicate using a SERIES of SOAP (Simple Object Access Protocol) messages through UDP and HTTPs, but not local IP addresses. Therefore, there is no IP address for WSD devices. This link can help: Just came across this article, I don't think it's true. Article and link articles explain it well. WSD works on IP. Our printer uses WSD but still has an IP address. Shadlowguy wrote: Just came across this article, I don't think it's true. Article and link articles explain it well. WSD works on IP. affic one after another and does not have a mechanism to forward missing or bad packets - top handshake and reliability advantage send package, peceived package, package (missing/bady) forward request, transfer completed (end). I think the simple answer to the posters here is: WINDOWS 8 and some Windows 7 ealy like to connect using WSD Article:WSD-based printing devices use the WSD port monitor by default. If the print device does not support the WSD port monitor is used instead. So my best guess is WSD changes the functionaling devices used to TCP/IPbeing being used together we forget sometimes they are two separate protocols and can operate separately. IP protocol is like home addresses where the email get sent and where it is going. TCP protocol is similar if you sent a message requesting a signature or request it, and you automatically sent the message again if you don't receive if Signature. WSD replaces TCP functions with its delivery controls. To use WSD you must provide an IP address and because it uses TCP as a backup when WSD does not work correctly, the TCP protocol is also set to the printer. WSD evices will try to use WSD and IP if it doesn't work, will try TCP and IP to transfer data. Page 2 Indeed yes! I just had this problem occur today, two relatively new Windows laptops with Win10, they were originally setup in a small office, saw the older Kyocera CopySta 300ci printer, perhaps due to kyocera driver istallation process, helping to find it correctly. Everything went well for 2 weeks, then both Win10 laptops apparently lost the ability to print. When I looked at the printer was office settings, I was surprised that it was this WSD at TCP/IPV4 as I expected. I'm not sure, but I also noted a really long line that almost looked like an experiment with a signature and shouldn't be a LAN at all as far as I know (I think IPv6 was also turned off by lan router like IPV6, unfortunately there were so many real-world problems cause better without it through the small business environment lan in
