Drupal pdf download module

This python 3 module will help you extract data from drupal 7 or 8 website. This data can be used later to back up or migrate to another CMS, such as Vaizey. Drupal is an open source CMS written in PHP. She has a long history and many followers. A large number of websites run on Drupal and have a significant development community. The product can be expanded, there are plenty of useful modules to improve the functionality of Drupal websites. Over the years, there have been a number of major versions of Drupal. At the time of writing, the most recent was Drupal 8. In the past, migration from one major version to another has been carried out on the ground. However, to move from an earlier version of 8, the user must follow the migration process, including creating a basic implementation of Drupal 8 first and then using additional data copying tools from the old website to the new one. While this should work in theory, the reality looks a little different. I own a few very clear drupal 7 websites. They use a number of modules from the standard repository, but not user code. Most of the content is simple stories. However, migration was quite ugly - a lot of content failed to end. What you did, it looked quite punk and definitely does not match the appearance and feel of my old websites. The blocks are gone. In short, the result takes a lot of additional work to get it right. I decided to go back to the old deployment of Drupal 7, which, of course, was easy, thanks to the fact that migration really involves a new instance of Drupal. That was the short-term solution. Given the efforts of migration, I decided to move all my websites to Django + Bragtail, which will give me much more freedom in managing my data and, I hope, will be a good long-term solution. To be honest, Drupal has lasted more than 10 years, so it wasn't a bad trip overall. But I hate to code in PHP, so getting rid of it for good fills my heart with joy. To achieve this movement from Drupal to Django, you need to extract the data from the first in some readable format. Fortunately, there are simple export facilities built into CMS. This python package uses them to download the data. There is a common API for processing any downloaded object, such as node, comment, term, etc., or simply sharpen everything like JSON into files. The task of shaping this extracted data into something suitable for Django or any other purpose you may have in mind is entirely yours. Currently, only Python 3 is supported. May Python 2 die with quiet dignity! Drupal 7 and 8 are currently supported. In theory, this module can work with previous versions of Drupal and may also work with some future ones. Your mileage may vary. package is available in PyPi. Just use pip to install (assuming you work in virtual environment Python 3): pip pip drupal_download First, you must activate the JSON REST API in Drupal. Naturally, both 7 and 8 will have different ways to achieve this (evil laughter!). Make the appropriate configuration changes and node apis endpoints. Make sure that you configure the authentication controls you want. Currently, the module supports the following methods: Anonymous - authentication is not required. This means that anyone can access you endpoint and download http basic data - the standard basic authentication session - cookie-driven authentication, the same in fact that you use when accessing drupal site interactive NB: I strongly recommend using HTTPS for all these communications. If you don't already have an SSL certificate and can't afford it, get it for free from Letsencrypt. For Drupal 7 you need to use the services module. While the same service module has a version for Drupal 8, it does not work. It looks like a gate abandoned in the middle. However, Drupal 8 includes API support for RESTful at the base. Naturally, it works a little differently from the service module. In particular, the services expose the index view to, say, nodes. This view contains only the information for each node of the bones. It also has a link to the view with the full details that the module follows. The Drupal 8 RESTful API on the other hand can export all fields to the main view. Read more about it here. Note that half cooked Drupal 8 port services causes the built-in RESTful API to be interrupted in some way if enabled. For faster downloads, it is recommended that you use larger page sizes in the view configuration. You can use the API from this module directly, thus: def data_callback(obj): # processes data dl = Drupal7DadaDownloader (john, 123, AuthType.CookieSession, data_callback) dl.load_data() Alternatively, there is a simple lint tool command that is sent with this module. You can call it this way: python3 -m download_drupal --help It will show some information for help. Calling it this: python3 -m download_drupal -b --username jane --password --auth-type CookieSsion -o example_node.json --drupal-version 7 will download all nodes from Drupal 7 website. 9.0.7-0 Check amount MD5 549a006d2d938baf606405b20c1d9ef8 SHA1 88c42 954e8cd18bc2eb0c585347e1842acb2815 SHA256 88665a0b7baf73e75 c 18000000000000000000000000000000000000000000000000000000000002811b5358fc428c69b7f356b75a88e40490a444f6f5555
