## Syma x5c drone manual

If you can't download directly through the X5C guide.pdf, try opening with the browser. Syma X5C Manual - Syma X5C Explorer is part of a four-engine quadcopter and propeller that are symmetrically positioned on each side. The drone also has a frame that is familiar to the quadcopter, which is X-shaped. And if you can see it at first sight, the Syma X5C Explorer looks slim, even if it was given the case with its flagship white color. But despite the subtle look, the drone has a body made of strong material. Not to mention, this drone also has legs as support while standing at ground level. The function of this leg protects the camera from a hard surface that can even damage the body block. Not enough with how safe the propeller is, this drone can also be fitted with a propeller protector on each side to prevent collisions with straight solid objects on the propeller, so the propeller can be safer. The description of the Syma X5C User Manual Language English format PDF File Download Syma X5C Explorer comes not only with additional features in the form of cameras that can be used to shoot and record video only, but Syma also gives other features that the button already exists in remote. Because it is designed for air photography too, this Syma X5C Explorer must surely have a stable ability to fly. The Syma X5C Explorer thus has 6 gyrosomes that are ready to make drones capable of flying shock even in the wind. The drone continues to use the battery as its main power source. The Syma X5C Explorer has a battery power of 3.7 volts and a capacity of 500 mAh. And with segitu capacity, the Syma X5W Explorer can fly for about 7 minutes. Then you can recharge the battery with a delivered USB cable buying. You can recharge your battery via a USB port on your computer or laptop, and you can also use the adapter, as when recharging your smartphone, or if you're out of the house, you can also use PowerBank more practically. The recharging process lasts about 100 minutes. The Syma X5C Explorer already has 4CH with a high frequency of 2.4 GHz data transmission. With this controller, you can control the Syma X5C Explorer within a 80-100 meter radius. In this remote, in addition to the controls to go down and rotate, there are also several key features that you can use for the sake of shooting in the air. In addition to the add-on, on the remote control, there is also a monochrome LCD that displays status as well as current information such as battery power, signal strength, selected mode, and selected speed, so you'll be more available for the current drone and controller status. For shooting, Syma X5C Explorer equipped with 2MP HD resolution With this camera, you can take photos or shoot videos from the air as high as possible. With the camera, you can easily easily an airy moment that you won't be able to find if you are below. You can use this feature by pressing the existing button on the remote control. The Syma X5C quadcopter instruction describes all the features and capabilities of this aircraft. It presents security techniques, remote control features, batteries, copter settings and many other features that will be useful for any owner. The instruction is primarily aimed at beginners who have not engaged in such devices before, but it can be useful to experienced users. The Syma PDF drone instructions The structure and design of the quadcopter are focused on a sufficiently high strength, thanks to which the device is able to withstand accidental damage. At the same time, this device also has good aerodynamic properties, allowing you to fly in open areas even in relatively strong winds. Another very important feature is the modular system used in this device. This means being able to quickly and easily change most components. Thus, the user can easily, without special equipment and skills to change failed items, remove them, replace, clean, maintain and so on. For the proper use of the quadcopter, it is recommended that you keep this guide and always have it with you during the flight, just in case. It should be remembered that this device does not belong to toys. It is a complex mechanism that requires adjustment, careful care and precise management. Otherwise, the device will not work as intended and can lead to injuries, damage to personal property and so on. This model's quadcopter is designed for children over the age of 14. Even then, the management of minors is subject to the strict supervision of an adult who can intervene at any time and thus prevent possible problems. It should be remembered that the operator is fully responsible for any copter actions, including those that may cause injury or damage to valuable property. The company is fully responsible for the performance of the device during its unpacking. The Symax X5C quadcopter is allowed in a vacant, open area or designated area. It is forbidden to use a quadcopter in prohibited areas such as airports, military bases and others. Flights are allowed at temperatures ranging from -10 to 40 degrees Celsius. It is not recommended to operate the aircraft in close proximity to any objects that may be damaged as a result of a collision with the device or which may damage the vehicle itself. Also, don't bring clothes, hair or hard items to the blades. In the first case, they themselves may be the second can damage the quadcopter. In the center of the front of the control panel is a switch that turns on the panel off. Slightly higher IS, the indicator, the current state of the device, as well as an alarm about possible problems. On the upper side surface is a plastic pen used to carry the device, as well as an antenna that increases the distance of control of the quadcopter. There are two buttons on the upper side surface on the left and right of the antenna. The left is responsible for switching the plane's speed mode, and the second activates the coup mode. On the front side, on either side of the switch/off are the main control sticks. The left is responsible for the set of height and descent on the helicopter, as well as for its rotation around its axis. The right stick is responsible for moving the quadcopter in a horizontal plane in any direction. By combining the action with the sticks, you can make the device fly in the right direction. Next to them are four trim tabs. Three of these serve to fine-tune the copter, and the last, the fourth, located to the right of the left control stick, is responsible for controlling the camera installed in this aircraft. The lower surface of the console occupies a relatively large screen that displays a variety of technical information that may be useful to the user. At the back of the console is a battery compartment, which is covered with a conventional plastic coating. The main thing in it - to install the batteries in the right position. To do this, the compartment itself indicates exactly how these power sources should be installed. Four AA batteries are required. The elements of interface 1-3 indicate the current settings of the aircraft. The display is reset every time the console is turned on, but the settings are not reset. No 4 - speed indicators. No 6-9 indicates the current direction of the aircraft, and No. 10-11 - the direction of its rotation around its own axis. No 12 is a speed indicator. If there is a letter L, a low speed is set, which is activated by default every time the helicopter is turned on, even if the high speed was activated at the stop. If the letter H is standing, a high speed is set, convenient for flying at high altitude and in open terrain. No 13 is an indicator of the current level of battery charging, and No. 14 is a control mode (for left-handers or right-handers). No 15 is a signal level indicator. The higher it is, the better the quadcopter will be managed. To turn the plane on, you must first activate the control panel. Then open the battery compartment on the body of the aircraft, insert the power device there, connect the power cable to the device and close the compartment. The helicopter must then be mounted on a flat surface, move 2-3 meters and take the remote control. It should be raised to the maximum position and immediately lowered to the lowest possible position. If LEDs after this outbreak, synchronization is not You need to turn off the helicopter and the control panel, and then repeat the procedure again. If the lights are only flashing on the helicopter, it has a very low battery level. It should be replaced or charged, after which you can try to repeat the procedure included. To replace the battery, the quadcopter must first be turned off with a switch on its case. Then open the compartment cover and disable the cable leading to the block itself. Only after that, you can remove the battery from the compartment and connect it to the USB cable that comes with the kit. The other end must be connected to an adapter, laptop or computer. In the last two cases, you have to make sure that your computer and laptop are always all the way through charging. If there is a need for an emergency outage, the first thing to do is to turn off the battery and then turn off the device. Also, do not charge the battery immediately after use. It should first cool to about room temperature. Protective bars are installed in special holes located on the body of the aircraft in the engine compartments. Each propeller has its own safety net. A simple installation is not enough, and besides they should be fixed using a bolt, which also comes full. The legs of the stand are installed in a similar way, but the holes for them are at the bottom of the case. Also for the legs there is no additional bolt attachments. This should be taken into account. After falling from a great height, the legs can fly away, it is recommended that they be immediately found and put in place. The quadcopter is controlled by sticks placed on the remote control. There are two routines, for left-handers and for right-handers. They are almost no different from each other. The only difference is that in left mode, most of the controls on the remote control are reflected. That is, the left stick will serve as the right and vice versa. To climb, lift the left stick up. The descent and landing is carried out when the same stick goes down. He is also responsible for the turns of the quadcopter around the axis. To turn left, tilt the stick to the left, and to turn right, you need to tilt the stick to the right. The right stick controls the horizontal movement of the helicopter. The tilt of the stick forward forces the helicopter to fly forward and vice versa. The device can also fly sideways, for which the right stick must be tilted left or right. The aircraft's behavior is adjusted with the help of trim tabs located next to the control stickers. If the device itself starts spinning around its axis without an additional operator command, you need to pull the trimmer in the opposite direction from the side of the rotation. For example, if the helicopter rotates to the left, the trimmer must be moved to the right Vice versa. If the device is flying forward, backward, left or right, you need to use the trim tabs next to the right stick. The side movement is controlled by a trimmer from the bottom of the control stick, and the forward or backward movement is controlled by a trimmer to the left of the right stick. They must be moved in the opposite direction to the copter movement. For example, if the device is flying forward on its own, you should move the trimmer to the left of the right stick backwards and vice versa. One of the main functions is protection from discharge. The device

starts flashing with LEDs when the battery level becomes critically low. You need to immediately return the device to the ground, put the power source on charge or replace it. The second useful feature is coups. They look very impressive. This mode is activated by pressing the right button at the top of the console. Deactivated in the same way. After turning the right stick loses its function and begins to be responsible for the direction of the coup. A special lock located on the underside of the aircraft's body is used to install the camera. There the device must be installed and connected with a built-in cable to the quadcopter. To do this, its case has a separate connector. You can shoot the camera in the same way, but in reverse order, only in addition, you need to press the retainer with your fingers. Keep in mind that the connection must be made on a disconnected quadcopter, otherwise the device will not be able to earn. The camera is controlled by a trimmer to the right of the left control stick. If you take it, the camera will take a picture of what it sees at the moment. At this time, the body will flash the LED light. If you lower this trimmer down, the LED will turn red and the camera will start shooting. There are two most common and basic problems: the lack of response to the user's actions and the slow (or incorrect response) of the aircraft to the actions of the operator. In both cases, first check the battery and battery levels in the remote control. If they are fine, in the first case, if there is no reaction, you need to completely disable the device and turn it on again. In the second case, the problem may be signal interference. Their source is not always obvious. It's a good idea to turn off your device, change the location of your flight, and try again. Once again.
