

Wolf slot machine games

In the not-too-distant past, slot machine players were the second-class citizens of casino customers. Jackpots were small, win rates were horrendous, and slot players simply weren't eligible for the kind of free bonuses -- free rooms, shows, meals -- commonly given to table players. But in recent decades the face of the casino industry has changed. Nowadays, more than 70 percent of casino revenue comes from slot machines, and in many jurisdictions, that figure is 80 percent higher. About 80% of first-time visitors to casinos head to slots. It is easy - just drop coins into the slot and press the button or pull the handle. Newcomers can find personal interaction with retailers or other players at intimidating tables - slot players avoid that. And also, the biggest, lifestyle-changing jackpots in the casino are offered on slots. Advertising The following article will tell you everything you need to know about slots, from the basics to the various strategies. We'll start with the square one, with a primer on how slot machine play works. How to play The most popular slots are penny and nickel video games along with four-quarter and dollar reel-spinning games, although there are video games in denominations of 2 cents, 10 cents, guarters and dollars and coil spinners up to 100 dollars. Most coil spinners take up to two or three coins at a time, while video slots can take 45, 90, and even 500 credits at a time. Almost all slot machines are equipped with currency acceptants - slide an invoice into the slot, and the equivalent amount of credits is displayed on a counter. On coil slots, press a button marked as playing a credit until you reach the number of coins you want to play. Then press the spin reels button, or pull the handle on those few slots that still have handles, or press a button marked play max credits, which will play the maximum number of coins allowed on that machine. In video slots, press a button for the number of payment lines you want to activate and a second button for the number of credits waged per line. A common setup has nine payment lines on which you can bet 1 to 5 credits. Video slots are also available with 5, 15, 20, 25, even 50 payment lines, accepting up to 25 coins per line. Many coil machines have a single winning line painted through the center of the glass in front of the rollers. Others have three payment lines, including five payment lines, each corresponding to a coin played. Symbols that stop on a payline determine whether a player wins. A common set of symbols be cherries, bars, double bars (two bars stacked on top of each other), triple bars and seven. A single icing on the payline, for example, could pay off two coins; the player could get 10 coins for three of the bars (a mixture of bars, double bars and triple bars), 30 for three single bars, 60 for three double bars, 120 for three bars, and the jackpot for three sevens. However, many of the stops on each reel will be empty spaces, and a combination that includes blanks pays nothing. Similarly, a seven is not any bar, so a combination like bar-seven-double bar pays nothing. Video slots typically have representations of five reels running on a video screen. Paylines not only run directly through the rollers, but also run in V, V upside down, and zigs and zags on the screen. Almost all have at least five payment lines, and most have more up to 50 lines by the mid-2000s. In addition, video slots usually have bonus rounds and scatter pays. The designated symbols trigger a scatter compensation if two, three, or more of them are displayed on the screen, even if it is not the same payline. Similarly, special symbols will trigger a bonus event. The bonus can take the form of a number of free spins, or the player can be presented with a second screen bonus. An example of a second-screen bonus comes in the long-popular WMS Gaming Slot Jackpot Party. If three Party noisemakers appear on the video rollers, the rollers are replaced on the screen with a grid of gift packages. The player taps the screen to open a pack and collects a bonus win. He or she can continue to tap packages for multiple bonuses until a pack finally reveals a pooper, which ends the round. The popularity of such bonus rounds is why video slots have become the fastest growing casino game of the last decade. When you hit a winning combination, the winnings will be added to the credit meter. If you want to collect the coins they show on the counter, press the button marked Cash Out, and on most machines, a bar ticket will be printed that can be redeemed in cash. In some older machines, coins still fall into a tray. Label Many slot players pump money into two or more adjacent machines at a time, but if the casino is crowded and others have difficulty finding places to play, limit themselves to a car. As a practical matter, even in a light crowd, it is wise not to play more machines than you can easily watch. Play too much and you might find yourself in the situation in front of the woman who was working up and down a row of six slots. He was dropping the coins in machine number six while number one, on the aisle, was paying a jackpot. There was nothing he could do when a passerby picked up a handful of coins from the first tray. Sometimes players who take a break for the rest room point a chair or leave some other sign that they will return. Make these signs take care of these signs. A bad comparison could follow if you play a machine that has already been so pointed out. Payout rates have increased since casinos realized it's more profitable to hold 5 percent of a dollar versus 8 percent of a nickel. In most cases in the country, slot players can figure out about a 93 percent win percentage, even if payments in Nevada run higher. Las Vegas casinos usually offer the highest average payments of all - better than 95 percent. Keep in mind that these are long-term averages that will hold on to a sample of 100,000 to 300,000 pulls. In the short term, anything can happen. It's not unusual to go 20 or 50 or more pulls without a single win on a reel-spinning slot, although payments are more frequent on video slots. Nor is it unusual for a car to pay back 150 percent or more for several dozen pulls. But in the long run, the planned percentages will hold up. The change in slots came in the computer age, with the development of the microprocessor. Previous slot machines were mechanical, and if you knew the number of stops - symbols or blanks that could calculate the chances of hitting the highest jackpot. If a car had three reels, each with ten stops, and a symbol on each reel was for the jackpot, then three jackpot symbols line up, on average, once every 10310310 pulls, or 1,000 pulls. On those cars, the big wins were \$50 or \$100, nothing like the big numbers players expect today. On systems that electronically connect machines in different casinos, progressive jackpots reach millions of dollars. The microprocessors that drive today's machines are programmed with random number generators that regulate winning combinations. It doesn't matter how many stops there are on each reel anymore. If he were to mount that old three-reel machine and ten stops with a microprocessor, we could put ten jackpot symbols on the first roller, ten on the second and nine on the third, and still program the random number generator so that three jackpot symbols aligned only once every 1,000 times. And on video slots, coil strips can be programmed to be the time it takes to make the odds of the affected game at a desired percentage. They are not bound by a physical coil. Each possible combination is assigned a number or numbers. When the random number generator receives a signal - anything from a coin that is dropped on the handle that is pulled - set a number, and the rollers stop at the corresponding combination. Among the signals, the random number generator works continuously, through dozens of numbers per second. This has two practical effects for slot players. First, if you leave a car, then seeing someone else hit a jackpot shortly after, don't worry. To reach the same jackpot, you needed the same fraction-of-a-second time as the winner. The are overwhelming that if you stayed in the car, you would never artish the same combination again. Secondly, because the combinations are random, or as close to random as possible to set the program. the chances of hitting any particular particular combination the same on every shot. If a car is programmed to pay its highest jackpot, on average, once every 10,000 pulls, your chances of hitting it are one in 10,000 on each draw. If you've been there for days and played 10,000 times, the odds on the next shot will still be one in 10,000. These guotas are long-term averages. In the short term, the car could go 100,000 pulls without letting go of the big one, or it could pay twice in a row. So, is there a way to make sure you hit big on a slot machine? Not really, but despite the elements of probability, there are some strategies that you can employ. We're going to cover them in the next section. In a modern slot machine, the chances of hitting a particular symbol or combination of symbols depends on how the virtual roller is set. As we saw in the last section, each stop on the actual roller can correspond to more than one stop on the virtual roller. Simply put, the chances of hitting a particular image on the actual roller depend on how many virtual stops correspond to the actual stop. In a typical weighted slot machine, the top jackpot stop (the one with the highest jackpot image) for each reel corresponds to only one virtual stop. This means that the chance to hit the jackpot image on a reel is 1 in 64. If all reels are set the same, the odds of hitting the jackpot image on all three reels are 1 in 643, or 262,144. For machines with a larger jackpot, the virtual roller can have many more stops. This greatly reduces the chances of winning that jackpot. Advertising The loss of empty stops above and below the jackpot image can correspond to more virtual stops than other images. As a result, a player is more likely to hit empty stops right next to the winning stop. This creates the impression that they have just lost the jackpot, which encourages them to keep gambling, even if the proximity of the actual stops is irrelevant. A machine's program is carefully designed and tested to get a certain percentage refund. The refund percentage is the percentage of money that is put in that is eventually paid to the player. With a refund rate of 90, for example, the casino would take about 10 percent of all the money put into the slot machine and give away the other 90 percent. With any refund rate below a 100 (and they're all under 100), the casino wins over time. In most gambling jurisdictions, the law requires reimbursement rates to be above a certain level (usually somewhere around 75 percent). The reimbursement rate in most Casino machines is much above the minimum - often in the 90-97 percent range. Casinos don't want their machines to be much tighter than their competitors' machines or players will take their business elsewhere. The dimensions for a particular slot machine are integrated into the program computer chip. In most cases, the casino cannot change the odds on a machine without replacing this chip. Despite popular opinion, there is no way for the casino to immediately strengthen a car. Even cars don't loosen on their own. That is to say, they are no longer inclined to pay the longer you play. Since your computer always pulls on new random numbers, you have exactly the same chance to hit the jackpot every time you pull the handle. The idea that a machine can be ready to pay is all in the player's head, at least in the standard system. When you hit slot machines in a casino, you'll have dozens of game options. Machines are available with a variable number of reels, for example, and many have multiple payment lines. Most machines with multiple payment lines allow players to choose how many lines to play. For the minimum bet, only the single line that runs straight through the rollers counts. If the player puts more money, he or she can play the additional horizontal lines above and below the main payline or diagonal lines running through the reels. For machines with multiple betting options. regardless of whether they have multiple payment lines or not, players can usually only benefit from the maximum bet. For this reason, gambling experts suggest that players always bet their best. There are several payment schemes in modern slot machines. A flat top or straight standard slot machine has a set payment amount that never changes. The payout jackpot in a progressive machine, on the other hand, constantly increases as players put more money into it, until someone wins everything and the jackpot is reset to a starting value. In a common progressive configuration, multiple machines are connected to each other in a single computer system. The money put in each machine contributes to the central jackpot. In some giant progressive games, machines are connected by several casinos throughout a city or even a state. Some slot-machine variants are simply aesthetic. Video slots work the same way as regular machines, but they have a video image rather than real rotating rollers. When these games first came out, the players were very wary of them; without the rotating rollers, it seemed that the games were rigged. Although rollers and handles in modern machines are completely irrelevant to the outcome of the game, manufacturers usually include them only to give players the illusion of control. These are just some of today's popular slot variants. Game makers continue to develop new types of with interesting twists and turns on the classic game. Many of these variants are built around particular themes. Now there are slot games based on TV shows, poker, craps and horse racing, just to name a few.
