×Sorry InterruptCSS Error ×Sorry InterruptCSS Error ×Sorry InterruptCSS Error If you have a Linux server that serves up files to users on the network, you may need a little extra protection. Here's how to install and configure Sophos AV on your Linux server. You may think that your Linux server is invulnerable to malicious code. You're wrong. Although the platform itself may not be directly affected if this server happens to give out files to users (via Samba, SSHFS, NFS, etc.), then users who are connected could easily fall victim to malicious files. It's a waiting nightmare. How do you avoid this on a Linux server? You install real-time antivirus/antimalware solutions like Sophos.Sophos antivirus for Linux is a free, command-line-only, real-time scanner for your server and desktop. The tool can be run in the background or the scan can be released manually. I want to guide you through the process of installing this piece of software so you can be sure (albeit slightly) that your server is less likely to contain malicious code. Keep in place that no server (regardless of platform) is 100% secure. Connected to the Internet or not, the server or desktop may be compromised. To that end, I don't think adding a piece of antivirus will be your end-to-end security measure for your Linux server. You must always be meticulous in your administrative duties. With that said, let's install. SEE: Security Linux Policy (Tech Pro Research) Getting software In order to obtain software, you need to go through the process of registering your email address. Finally, you will find yourself with a download link. This can be a little more complicated if your server is without a graphical user interface. The download link contains a unique key (associated with your email address), so you can't just copy or paste it and use the wget command to download the file to the server. Instead, you can download it to a desktop computer on the network, and then use scp to copy the file to the server. This is done as follows: scp sav-linux-free-9.tgz USER@IP:/path/to/save/file Where USER is a user on the remote server, IP is the IP address of the server, and /path/to/save/file is the actual path where you will save the file (such as the USER's home directory). Once this file has been uploaded to the server, you can extract it by using the command:tar xvzf sav-linux-free-9.tgz Installing the SophosStzísávka file .tgz creates a new directory, called sophos-av. Change to this directory with cd sophos-av command. Inside this directory you will find the necessary installation script; run this script with sudo sh install.sh. You'll see a welcome screen asking you to type Enter to see the EULA message (Figure A). Image AThe Sophos installer welcome screen. When viewing the license, press spacebar to browse and then type Y to accept. You will then be asked where you would like to install Sophos, but if you want to create your own bash scripts and cron jobs for regular scanning, this is your best bet. When prompted, type either Y and press Enter, or just type Enter (because yes is the default). When you enable access scanning, Setup prompts you to specify the location of the update. You have three options: Sophos - download definition updates from official Sophos servers. Your own server - Download definition updates from the local server. None -- do not download definition updates. If you are not willing to set up an update server, I would recommend going with the default (Sophos). Either enter with and press enter, or just meet Enter.The next question wants to know if the installation will be free or supported version of Sophos. The default value is supported that we do not install. Type f and press enter to install the free version. Finally, you can configure the proxy server (if necessary). If no proxy server is required, type N and press enter (or just type Enter). Installation will begin and finish with Sophos Antivirus Installed. The installation will allow everything you need, so when you receive the installation completed, Sophos is good to go. Add an email address with a warning You may have noticed that you were unable to add an alert email address during setup. This is because it is done after installation. You can add multiple email addresses to receive alerts, as well as an email server (if necessary). By default, Sophos will use SMTP on localhost (port 25). If there is a problem, you can set up an e-mail server with the command:/opt/sophos-av/bin/savconfig set EmailServer SERVER_ADDRESS Where SERVER_ADDRESS is the actual IP address or domain of your e-mail server. You can also add email addresses, such as recipient alerts, with the command:/opt/sophos-av/bin/savconfig to add E-mail EMAIL@ADDRESS where EMAIL@ADDRESS is the actual email address to add. If you need to add multiple addresses, add them all to the command above (separate them with a space). SEE: Cyber Warfare Defense: As the cybersecurity elite tries to prevent digital apocalypse (free PDF) (TechRepublic)Your Linux server, saferConnets, your Linux server is now a little safer. Sophos AV runs in the background, doing a real-time scan of your server. If it finds a disputed file, it will take action and notify you by email. Again, I must mention that this should not give you a false sense of security. If the device is turned on, it is vulnerable. If you have users who share files on this computer, even more capable malicious code. Do everything in your power to keep your users and data safe. The administrator's work is never done. Strengthen your organization's IT security by keeping up with the latest cybersecurity news, solutions, and best practices. However, clamav can be analyzed and used by other engines to kill auxiliary judgment. sophos for The 以杀-windows下毒. 关于,sophos的web GUI面,我没的来,是系原的,也的是已的了. Linux servers come in many flavors, from Red Hat to SUSE to Ubuntu. They all share a common reputation as largely immune to the malware problems that plague Windows. So it's no surprise that many IT professionals are asking if it's really worth installing antivirus software on their Linux servers. As it turns out, the answer, more often than not, is yes. One reason to consider installing Linux antivirus is that malware for Linux actually exist. It's much less common in the wild than Windows malware, but rootkits like the one that targeted the SSHD daemon earlier this year show that it's a real threat. You want to explain to your boss that the critical server was destroyed because you didn't think it would get infected? While internal Linux servers have little risk of exposure to Linux-specific malware, public Web sites are the main target. An average of 16,000-24,000 URLs are compromised by malicious code every day, according to SophosLabs. Cyber criminals target vulnerable components of websites, such as content management systems (such as WordPress and Joomla), application environments (PHP), control panels (Plesk and cPanel), and even the ubiquitous Apache web server. Web sites should therefore always be protected by antivirus software and ideally by a web application firewall. Even if the Linux server is not infected on its own, it can still put your users at risk. Have you heard the story of Typhoid Mary, a woman who never gets sick herself but carried a typhoid infection and spread it to more than 50 people? Similarly, Linux servers can function as carriers, especially when they act as file servers or document stores. In fact, SophosLabs tells us that most malware detections on Linux systems are for Windows malware. Finally, compliance regulations such as PCI-DSS may simply require you to install antivirus software on systems that store or process sensitive data. If you do not install antivirus software in these cases, your organization may be subject to fines and/or legal liability in the event of data loss. Fortunately, Sophos Antivirus for Linux has a small footprint and minimal impact on system speed. Basically, you won't know it's there – except, of course, when it detects and blocks a threat from infecting a server or spreading to your users' workstations. Sophos Antivirus for Linux is available as part of Sophos Server Protection. Try it for 30 days for free! Free!
