## Normalize 3d array python

sklearn.preprocessing.normalize(X, norm='l2', q, axis=1, copy=True, return\_norm=False). Read more in the user's guide. X-array-like settings, sparse matrix, form of n\_samples, n\_features Data for normalization, element by element. scipy.sparse.matrix should be in CSR format to avoid optional copy. norm='l1', 'l2', or 'max', optional ('l2' by default) Norm used to normalize each non-zero sample (or each non-zero function if axis 0), axis0 or 1, optional (1 default) axis used to normalize data together. If 1, independently normalize each sample, otherwise (if 0) normalize each function. copyboolean, optional, default True set to False to perform line normalization and avoid copying (if the input is already numpy array or scipy.sparse matrix, and if axis 0). return\_normboolean, by default False whether, to return the calculated norm returns to the X-array-like, sparse matrix, form of n\_samples, n\_features 'Normalized X entry', form of n\_samples if the axis 1 still n\_features array of norms along this axis for X. When X is rare, NotImplementedError will be raised for the norm 'l'. Notes To compare different scalers, transformers and normalizers, plot\_all\_scaling.py see © 2007 - 2020, scikit-learn developers (license BSD). Normalize the 2D numpy array, so that each column is on the same scale (linear stretch from the lowest 0.0 to the highest value of 100). You can't do this this time. In this tutorial we learn how to change arrays, normalize the lines that broadcast and softmax. The two common numpy functions used in deep learning are np.shape and np.reshape(). Form forms is used to form (measuring) the X. Reshape matrix or vector (...) to change the amtrix or vector into some other dimension. For example, in computer science, a standard image is represented by a 3D array of shapes (length, height, depth). However, when you read an image as an input algorithm, you convert it into a shape vector (height length, 1). In other words, you deploy or change a 3D massif into a 1D vector. Thus, we will implement a function that takes the input of the form (length, height, depth) and returns the vector of form (length height, 1). For example, if you wanted to change the form A array (a, b, c) into a form vector (a,b,c) you would do: A.reshape ((A.shape)A.shape,A.shape,A.shape (A.shape) A.shape (A.shape) - b A.shape (A.shape) - C To implement the above feature, we write a simple few lines of code: def image2vector (image): A-image.reshape (image.shape[0]image.form.1) returns A To test our above function, we'll create a 3 by 3 by 2 array. Typically, images will be (num\_px\_x, num\_px\_y, 3) where 3 represents RGB values: image - np.array ([11, 12], No. 13, 14, 15, 16, 21, 22, 23, 24, 25, 26, Print 31, 32, No 33, 34, 35, 36) printing (image2vector (image)) print (image.form) print (image2vector (image)) As a result we get: (2) (31) (33) (3, 3) 2 (18, 1) (18, 1) (18, 1) As you can see the shape of the image (3, 3, 2) and after we call our function it changes to a 1D array of shapes (18, 1). Line normalization: Another common method used in machine learning and deep learning is to normalize our data. This often results in better performance because the gradient descent converges faster after normalization. Here, by normalization, we mean changing x to q (frac(x) (dividing each x string vector to its norm). For example, if: \$x(1) xz np.linalg.norm (x, axis No. 1, keepdims = True \_normalized(2)(56) Frak(3)(5) th frak(4)(5) frak(2)(56)(4)(6)(56)(56) {2} gost(56)(56) {2} if you ask(3), as we got the division by q (5) or division by q (sqrt(56)), the answer is: \$4.2 - \$5 \$ and: \$ (sqrt) - 2.2 x 4.2 euros(56) \$ Next we implement a feature that normalizes each row of the x matrix (to have a unit length). After applying the 2nd function to the input x matrix, each x range must be a unit length vector: def normalizeRows (x): x\_norm - np.linalg.norm (x, ord No 2, axis No 1, keepdims = True) x/x\_norm return x To check our feature, we'll call it with a simple array: x np.array (0, 3, 4, 1, 6, 4) print (normalizeRows (x)) We can try to print shapes x\_norm and x. Вы узнаете, что они имеют разные формы. Это нормально, учитывая x\_norm что он принимает норму каждого ряда x. Таким x\_norm имеет такое же количество строк, но только 1 столбец. Так как это сработало, когда мы разделили x\_norm? Это называется вецинацией. Функция Softmax: Теперь мы будем реализовывать функцию softmax, используя пирму. Вы можете думать о softmax как о нормализуемой функции, используемой, когда вашему алгоритму необходимо классифицировать два или более классов. Вы узнаете больше о softmax в будущих учебниках. Mathematical softmax functions: \$ text{for } x \in \mathbf{matrix}^{\wedge 1\text{limes } n} \{text{softmax}(x) = softmax(\begin{bmatrix} x\_1 & \dots & x\_n \end{bmatrix}) = \\$\\$ \\$\\$ = begin{bmatrix} x\_1 & \dots & x\_n \end{bmatrix} end(bmatrix)} x\_{(11)} \& x\_{(12)} \& dots \& x\_{(13)} \& dots \& x\_{(21)} \& x\_{(22)} \& dots \& x\_{(23)} \& dots \& x\_{(2n)} \& dots \&
